Immediately below the Cataracts there is another small island in the river, which enjoys a celebrity scarcely inferior to that of Philæ; we mean Elephantiné, now called by the Arabs Djeziret-el-zahir or the Flowery Island, by reason of its luxuriant vegetation. In the time of Psammeticus this islet formed the last fortified place in his dominions, and under the Romans it was garrisoned by three cohorts. In point of size, it is so diminutive that, according to Champollion, "il formerait à peine un parc convenable pour un bon bourgeois de Paris.[4]" Heaps of rubbish mark the site of the town supposed to have given birth to the head of the Elephantine dynasty, and until recently there were remains of two temples covered with hieroglyphics, and approaching in design to the earliest temples of Greece. But within the last few years both these monuments have been destroyed in order to construct a barrack and magazine at Syene; and a little temple, dedicated to Knuphis by Amenophis III., has also disappeared.[5] The only remnants left are two steps of a granite gateway, belonging to another temple of Knuphis, Saté, and Anuké,[6] dedicated under Alexander, the son of Alexander the Great. A wall of the quay, however, exhibits, intermingled and mutilated, the wrecks of several ancient edifices of Elephantiné, constructed under Mœris, Mandoueï, and Rhamses the Great; and in the remains of a chamber adjoining the stair of the quay are several curious hieroglyphic *proskynemata*, as well as in the inscription of a mutilated stelé originally erected in honour of Mandoueï. The quarries of Elephantiné were worked in a very early age, and furnished the materials for many celebrated monuments. Amongst these may be mentioned the famous monolithic temple at Saïs, formed of a single block of granite, the removal of which from Elephantiné to the Delta employed two thousand men for the space of three years. On the wall of an ancient quay, over a flight of steps leading to the river, may still be seen the nilometer which is mentioned by Strabo. Physically considered, Elephantiné is more properly the southern extremity of Egypt than Philæ; for it is the last projection of the granite rock which forms the natural division between Egypt and Nubia, and beyond it the limestone tract of country commences.[7]

On the eastern or right bank of the Nile, nearly opposite to Elephantiné, stands the town of Assouan or Ossouan, the Syené of the Greeks, and the Souan of the Copts, in whose language the word signifies "the opening." From its proximity to the northern tropic it was fixed upon by Eratosthenes as the point of departure for his admeasurement of a degree of the meridian in order thence to calculate the circumference of the earth; and here also, according to Strabo, was the well which, as the gnomons cast no shadows at noon, marked the summer solstice.[8] At Syene may still be seen the ruins of a temple consecrated to Knuphis and Saté, under the Emperor Nerva. This monument, though it indicates an extreme decline of art in Egypt, is nevertheless exceedingly interesting, first, because it is the only one which bears the hieroglyphic legend of Nerva; secondly, because it contains the phonetico-hieroglyphic name of Syené, viz. *Souan*, the same with the Coptic, and the root of the Syene of the Greeks and the Assouan of the Arabs; and, lastly, because the symbolic name of this town, resembling the plummet line of an architect or mason, seems to allude to the position of Syene under (or nearly under) the tropic, and to the famous well into which the sun's rays descended vertically at noon on the day of the summer solstice. On some granite rocks in the neighbourhood, Champollion discovered the homage of an Ethiopian prince called Memosis, to Amenophis III. and Taia his queen; an act of adoration to Knuphis, the local god, for the safety of Rhamses the Great and his children; and several *proskynemata* of private individuals, as well as public functionaries, to the divinities of Syené and the Cataract.[9] For several centuries after the Arabian invasion, Assouan continued in a flourishing condition; but under the Fatemite caliphs it became a prey to intestine divisions, and has long been reduced to a state of the utmost wretchedness.[1]

---

[1] Belzoni's *Travels*, p. 347, et seqq. where an interesting account will be found of this difficult, and, as the result proved, perilous operation.

[2] *Recherches*, p. 279. The inscription consists of a petition from the priests of Isis to Ptolemy Euergetes II. (B. C. 125 or 126), praying him to release them from the exactions of the magistrates and military officers stationed in the Thebaid, and to permit them to erect a *stelé* or *cippus* in commemoration of the equity and beneficence of their sovereign; a prayer which the existence of the commemorative obelisk proves to have been granted.

[4] *Lettres écrites d'Egypte et de Nubie*, p. 171.

[5] *Lettres*, ubi supra; also, pp. 111 and 382.

[6] Each city and place of Egypt had its patron. Knuphis and Saté reigned at Elephantiné, Syené, and Begheh, and their jurisdiction extended over all Nubia; Phré presided at Ibsamboul, Derri, and Amada; Phtah, at Ghirscheh; Anuké, at Maschaket; Thoth, the superintendent of Knuphis, over the whole of Nubia, having his principal fiefs at Ghebel-adheh and at Dakkeh; Osiris was lord of Dandour, Isis queen at Philæ, Hathôr at Ibsamboul, and Malouli at Kalabschir.

[7] *Description de l'Egypte*, Antiq. p. 8. Girard, *Mém. de l'Acad. des Sciences*, tom. ii. p. 185, 1817. *Encyclopædia Metrop.* art. *Egypt.*

[8] This is not strictly correct, as the ancient town of Syené, though somewhat to the south-west of the modern town of Assouan, is 37′ 23″ north of the tropic; so that, during the summer solstice, there must be some shadow at noon, though it is scarcely perceptible.

[9] Namely, Knuphis, Saté, and Anuké. (Champollion, *Lettres d'Egypte*, p. 171.)

Descending the Nile about twenty-seven or twenty-eight miles below Assouan, we reach Koum-Ombo, which stands on the site of the ancient Ombos, upon the right bank of the river. All the lower part of the ancient town, however, excepting that which has been washed away by the river, is now covered with a mound of sand, as its modern name indeed implies. But two temples, surrounded by a brick wall of great thickness, have escaped the general destruction, and both belong to the Greek epoch. The larger, which is of beautiful architecture, and has a fine effect, was commenced by Ptolemy Epiphanes, continued under Philometor and Euergetes II., and appears to have been completed during the reign of Soter II., whose name, with that of Cleopatra his queen or sister, may still be detected on some of the bas-reliefs. This temple, which is formed of a greyish sandstone, differs from every other building of the same kind in Egypt, in having two entrances, and consisting of two connected though distinct and perfectly symmetrical structures. It appears to have been consecrated to two triads, each of which had a distinct division or compartment allotted to it; the one, composed of Sevek-Ra, with the crocodile's head (the primordial form of Kronos or Saturn), Hathôr or Venus, and their son Khons-Hôr; the other, consisting of Aroëris, the goddess Tsonenufré, and their son Pnevtho; and both together constituting the saviour gods of Ombos. The crocodile observed on the Roman medals of the Ombite nome is the sacred animal of the principal god Sevek-Ra. In the dedications, and in the cartouches or elliptical rings sculptured on the cornice of the pronaos, Cleopatra the wife of Philometor has a surname which can only be the Greek *Tryphœne* or *Dropion*,[2] but the former is considered as the more probable interpretation. This surname is repeated thirty times. The smaller temples of Ombos, like one of those at Philæ and the temple of Hermonthis, was a *Mammisi*, or sacred edifice representing the birth-place of the young god of the local triad; in other words, a terrestrial image of the spot where the goddesses Hathôr and Tsonenufré had given birth to their sons Khons-Hôr and Pnevtho. From ignorance of the local mythology, the authors of the *Description de l'Egypte* supposed that this temple had been dedicated to Isis and her son Horus.

Edfou or Edfu, the *Apollinopolis Magna* of the Greeks, is situated on the western or left bank of the Nile, about thirty-three miles below Koum-Ombo, and two miles from the water's edge. An ancient quay, with a flight of steps down to the river, and two temples at right angles to each other, but half buried in the sand, still remain. The larger of these is twice as long as it is broad, measuring about 440 by 220 feet; its largest columns are six feet four inches in diameter, twenty-one feet in circumference, and forty-two feet in height; and, as at Philæ, Denderah, and other places, its roof is covered with peasants' huts, whilst the openings originally intended for the admission of light serve as sinks for the reception of filth. The two lofty pylons, which are conspicuous from the river, and the thirty-two columns of the peristyle to which they lead, form altogether a magnificent perspective.[3] But this temple, the massive grandeur of which is so imposing, bears, nevertheless, several indications of the decay of Egyptian art under the Ptolemies, to whose epoch it entirely belongs; no trace of the ancient simplicity is discernible; and a profusion of elaborate but ill-conceived ornaments marks the transition from the noble gravity of the Pharaonic monuments to the fatiguing and endless *papillotage* of later times. The most ancient part of the decorations, namely, the interior of the naos and the right exterior side, belong to the reign of Philopater: the work was continued under Epiphanes, whose legends cover part of the shafts of the columns and the interior tablets of the right partition of the pronaos; and it was at length completed under the reign of Euergetes II. The sculptures of the exterior frieze and on the exterior walls of the pronaos were executed under Soter II. to whose reign also belongs the gallery on the right of the court before the pronaos: the gallery on the left, and indeed all the sculptures upon the two massive pylons, are of the age of Philometor. The wall of the enciente which surrounds the naos is entirely covered with sculptures, which (particularly those of the interior face) date from the reign of Soter II. and of Ptolemy-Alexander I. and contain the names of their respective queens, Cleopatra and Berenice. This magnificent edifice was consecrated to a triad composed of the god Harhat, or celestial science and light personified, the goddess Hathôr, the Egyptian Venus, and their son Harsont-Tho or Horus, answering to the Eros of the Greek and Roman mythologies. The lesser temple of Edfou, called the Typhonium,[4] is one of those smaller edifices called *Mammisi*, which were always erected beside the great temples where a triad was adored. The Mammisi of Edfou represents the infancy and education of Harsont-Tho, with whom flattery has associated Euergetes II. as sharing the caresses of the gods of every order. The large temple of Edfou is dedicated to Aroëris, the Apollo of the Greeks.[5]

Six miles lower down the river, on the opposite or right bank, is El-kâb, the ancient *Elethya*; but the remains of its two temples have disappeared, these structures having lately been demolished in order to repair the quay of Esneh, or for some other recent erection. Not so much as a column has escaped; and the entire temple, situated outside the town, has shared the same fate. It appears, however, from fragments of inscriptions, that the temple of Elethya, dedicated to Sevek or Saturn, and Sowan or Lucina, belongs to different Pharaonic epochs, and that those included in the city had been constructed and decorated under the reign of Queen Amenseh, under that of her son Thouthmosis III., called also Mœris, and under the Pharaohs Amenophis-Memnon and Rhamses the Great. Amyrteh and Achoris, two of the last kings of the Egyptian race, repaired these ancient edifices, and added some new constructions; but nothing attributable to the Greek or Roman periods has yet been discovered. The small peripteral temple which stood in the sandy plain about a mile and a half to the north of the town belonged to the age of Mœris. But by far the most remarkable antiquities of Elethya are the sepulchral caverns or *hypogœa*, excavated in an insulated hill, of the common sandstone of the country, at the distance of about four hundred yards to the south-south-west of the town. These tombs belong to a very remote period, and in the variety and richness of their decorations rival those of Thebes; with this difference, however, that, instead of religious and military subjects, those of a familiar and domestic kind are alone represented. The first of these visited by Champollion and his party was the one whose painted bas-reliefs, relative to agricultural labours, fishing, and navigation, have been published by the Egyptian Commission in the French national work.[1] This tomb, which is of high antiquity, had been excavated for the family of a hierogrammatist named Phapeh, attached to the college of priests at Elethya.[2] A second *hypogœum*, which proved to be that of the high priest of the goddess Ilythia or Elethya, from whom the town originally derived its name, bears the date of the reign of Rhamses-Meiamoun,[3] and exhibits a multitude of family details, with some agricultural scenes, not in the purest taste.[4] The tomb adjoining this is still more interesting in an historical point of view. It belonged to a person named Ahmosis, son of Obschneh, chief of the boatmen of the Nile, who appears to have been a great personage in his day. In the remains of an inscription, this Ahmosis recounts his history for the benefit of all persons present and future, and states some particulars which fix the date at which he lived, namely, under the last king of the seventeenth dynasty, who overthrew the cruel tyranny of the Shepherds, and delivered Egypt from those remorseless barbarians. Another *hypogœum*, nearly in ruins, made Champollion acquainted with four generations of great personages who governed under the title of princes of Elethya during the reigns of the first five sovereigns of the eighteenth dynasty, viz. Amenoph or Amenoftep I. Thouthmosis I. Thouthmosis II. Thouthmosis III. or Mœris, and Ranofreh, daughter of Queen Amenseh, and sister of Mœris. All these royal personages are successively named in the inscriptions on the tomb, and form as it were a supplement in confirmation of the genealogical table of Abydos discovered by Mr Bankes.[5]

[4] Jomard, *Description de l'Egypte*, i. 5, 30.

[5] Champollion, *Lettres d'Egypte*, pp. 109 and 191. Both the temples at Edfou are in a high state of preservation; but Mr Hamilton, in his learned work upon Egypt, has entirely mistaken the meaning of the sculptures (*Egyptiaca*, p. 87); and the same thing may be observed of Jomard in the *Description de l'Egypte*.

Esneh or Esné, the ancient *Latopolis*,[6] and the present capital of Upper Egypt, is about thirteen miles below El-kâb or Elethya, and stands in a plain where the valley is nearly four miles and a half in width. Owing to the neglect of the canals requisite for the irrigation of the soil, which is not now reached by the inundation, the surrounding country had been reduced almost to a desert, and the town itself would probably have been abandoned, but for its port and the trade carried on by means of the Nile. Under the vigorous administration of Mehemmed Ali, however, the canals have latterly been repaired, and various products, including cotton, raised on ground which was not long ago a sandy waste, apparently irreclaimable for the purposes of cultivation. At Esneh there are two temples; one of vast dimensions, which, the great Ammon be praised, has escaped destruction from having been converted into a cotton magazine; and another, much smaller, but remarkable for the peculiarity of its hieroglyphics. Both contain some of those symbolical zodiacs which have so greatly perplexed the whole tribe of Egyptian antiquaries. According to conjectures founded on a particular mode of interpreting the zodiac on the ceiling of the large temple, this monument has been regarded as the most ancient in Egypt; but the style of the sculptures, and, above all, the hieroglyphical inscriptions, prove that, in reality, it is one of the most modern to be found in that country. The latter, indeed, leave no doubt that the masses of the pronaos were raised under the reign of the emperor Claudius,[7] to whom there is a dedication in large hieroglyphics on the entrance, and that the corner of the façade, and the first row of columns, were sculptured under the emperors Vespasian and Titus; the posterior part of the pronaos bears the legends of the emperors Antoninus, Marcus Aurelius, and Commodus; some columns of the interior were decorated and sculptured under Trajan, Hadrian, and Antoninus; and, with the exception of some bas-reliefs, which belong to the epoch of Domitian, all those on the partitions of the right and left of the pronaos contain images of Septimius Severus, and of Geta, the brother of Caracalla.[8] The construction of this temple dates from the time of Claudius, and its sculptures come down as late as that of Caracalla. The remains of the naos, however, belong to the epoch of Ptolemy Epiphanes; but that is only as yesterday compared with the date which some fanciful antiquaries had assigned to this monument. On one of two columns, however, whose shafts were almost entirely covered with hieroglyphics arranged artificially, Champollion discovered a commemorative record of a dedication of an ancient temple by Mœris, otherwise called Thouthmosis III.; and in the quarter of the town known by the name of Sheikh-Mohammed-Ebbedri, he also found a dedication of Thouthmosis II. which, like the former, must have belonged to some old Pharaonic monument of Esneh. The great temple of Esneh was dedicated to one of the chief forms of the divinity Knuphis, who is described as *neven-tho-Sné*, or lord of the country of Esneh.[9] This place is also remarkable on account of a large Coptic convent, supposed to have been founded by the disciples of Pachomius, and to possess the bones of the martyrs who suffered during the persecutions of Diocletian.

At a small distance from the Nile, in the third expan-

---

[1] *Description de l'Egypte*, p. 7.

[2] In Egyptian *Sowan-kah*, or priests of Lucina, the goddess who was worshipped at Elethya.

[3] *Meiamoun* is an epithet, and means literally "beloved by Ammon," or Jupiter.

[4] Among the scenes represented on this *hypogœum* is one of the threshing or treading out of sheaves of corn by oxen, below which, in hieroglyphics, almost all of which are phonetic, is a chançon which the conductor of the oxen on the threshing-floor is supposed to sing. The ditty is addressed to the animals, and is as follows:—

Tread out the grain, ye oxen, tread it faster;
The work is yours, the bushels go to master.

This is not very brilliant poetry, we admit, and, probably, our translation has not improved it; but what occupies five lines in the original hieroglyphics we have found no difficulty in compressing into two; and the specimen is at least curious.

[5] Champollion, *Lettres d'Egypte*, pp. 109, 194, 382. Hamilton, *Egyptiaca*, p. 90, et seqq.

[6] *Esné* or *Sné* is the pure Egyptian name, and may be still read on all the columns and bas-reliefs of the temple. The Greek name of *Latopolis*, or *Letopolis* (for it is spelled both ways), is supposed to have been formed from *latus*, a species of fish held in veneration at this place. (*Egyptiaca*, p. 106.)

[7] In the hieroglyphic ovals or rings the name is *Cæsar Tiberius Claudius Germanicus*.

[8] When Caracalla assassinated his brother Geta, he caused the name of the latter to be proscribed throughout the whole empire; and this proscription appears to have been executed to the letter even in the depths of the Thebaid; for the ovals containing the name of this unfortunate prince have almost all been carefully defaced and hammered out. "Mais ils ne l'ont pas été au point (says Champollion) de m'empêcher de lire très-clairement le nom de ce malheureux prince: L'EMPEREUR CESAR-GETA *le directeur*." (*Lettres d'Egypte*, p. 200.)

[9] The titles by which the Knuphis of Esneh is qualified are "lord of the country of Esneh, creator of the universe, vital principle of the divine essences, support of all worlds," &c. With this god are associated the goddess Neïth, and the young Hâké, who complete

sion of the valley, is situated Ermont or Erment, upon the site of the ancient *Hermonthis*, the capital of a nome or department of the same name, and the see of a Coptic bishop. A temple of moderate dimensions, but of peculiar design, and distinguished for the beauty of its columns and sculptures, still remains. This temple is a *Mammisi* consecrated to the goddess Ritho, and, as the bas-reliefs prove, constructed and sculptured in honour of Cleopatra the daughter of Ptolemy Auletes, when she gave birth to Cæsarion, her son by Julius Cæsar. The triad here adored consisted of the god Mandou, the goddess Ritho, and their son Harphreh; and Cæsar, no doubt, wished to be the Mandou of the new Ritho, as Cæsarion was the Harphreh of both. "Du reste," says M. Champollion, who waxes facetious on the occasion, "c'était assez l'usage du dictateur Romain de chercher à compléter la triade, lorsqu'il non contrait surtout des reines qui, comme Cleopâtre, avaient en elles quelque chose de divin, sans dédaigner pour cela les joies terrestres." The body of the temple is still entire, and its cella consists of two compartments, a larger and a smaller, but some of the columns have been overturned. The import of the hieroglyphical inscriptions is very fully stated by Champollion.[1] This temple also contains a zodiac, the epoch of which, if it were considered determinable by such fanciful calculations as those we have already alluded to, would be altogether incredible.[2] Near to these ruins is a Christian church, which has been constructed out of the spoils of Grecian as well as Egyptian temples.

In the broadest part of the section of the valley forming its third enlargement, where the Nile is about four hundred and fifty yards in width, and runs from south-west to north-east, between Kournah or Gournah on the north, and El-Nahariyah on the south, the splendid remains of Thebes, the wonder of antiquity, a city the date of whose destruction was long anterior to the foundation of most other cities, are spread over a large area occupied by nine distinct townships, viz. El-Akaliteh, Nacah-Abu-Hamud, Konm el-baïrat, and Medinet-Habou to the west; Kournah or Gournah to the north; Luxor or El-oksor close to the river's edge; and Kafr-Karnak and Medamud on its eastern side.[3] The most remarkable of these places, with the Titanian ruins which are spread over their surface, we shall now endeavour as shortly as possible to describe.

At Ákaliteh the remains of an ancient hippodrome or race-course are visible, and at its northern extremity is Medinet-Habou, or the Town of the Father, containing the remains of a castellated palace with embattled walls,[4] and a temple with propyla of gigantic dimensions, besides majestic colossal figures, caryatides, and long rows of columns richly ornamented. This temple, which may be the Memnonium of Strabo, is in size and massiveness inferior only to that of Diospolis, but fully equal to it in the richness and variety of its sculptures. An outward inclosure or brick wall seems to have contained three distinct though connected buildings, to which have been arbitrarily assigned the respective names of the chapel, the palace, and the temple. A small pronaos, a propylon, and a portico, conduct as usual to the adytum of the chapel, which, from its size, would in any other place deserve to be classed amongst the temples. The palace was only approached by a side doorway from the pronaos of the chapel until the principal entrance from the plain, which had been blocked up with sand, was opened by the indefatigable Belzoni.[5] Of this building one tower only remains. It is divided into three stories, in each of which are two apartments. The stone pavement of the lower rooms is still perfect, but the upper floors and the wooden beams which supported them have entirely disappeared. The interior walls are not covered with such a profusion of sculptures as those without. The great gateway of the temple, which faces the palace at the distance of about three hundred feet, is covered with the usual sculptures; it is about a hundred and fifty feet in length and sixty in height, and conducts into a court which is about a hundred and twenty feet square. On either side there runs from this gateway to the next a colonnade; that on the right consisting of eight pilasters, to each of which is affixed a mitred statue of Thoth or Hermes, and that on the left of as many columns, each richly sculptured. The soffites and walls of these colonnades are also crowded with sculptures, the forms and colours of which are well preserved.[6] In the chapel, which appears to have been a work of the fourth century before our era, all the bas-reliefs still extant represent king Nectanebo, of the thirtieth or Sebennytic dynasty, adoring Ammon-Ra, the sovereign of the gods, and receiving the gifts and benefactions of all the other divinities of Thebes. But adjoining to it there is a pylon of moderate dimensions and fine proportion, which, having been erected under the domination of the Ethiopian king Taharaka (the Tirhakah of Scripture), in the seventh century before our era, contains, in the inscriptions and bas-reliefs which decorate the faces of the masonry, and also the gateway which separates them, the names, titles, and praises of this invader, which were afterwards proscribed when the Saïtes ascended the throne of the Pharaohs. On the masonry of the

---

the triad adored at Esneh. "C'est aux mêmes divinités," says Champollion, "qu'était dédié le temple situé au nord d'Esnéh, dans une magnifique plaine, jadis cultivée, mais aujourd'hui hérissée de broussailles qui nous déchirèrent les jambes, lorsque nous allâmes le visiter, en faisant à pied une très-longue course du Nil aux ruines, que nous trouvâmes tout nouvellement devastées; ce temple n'est plus tel que la Commission d'Egypte l'a laissé; il n'en subsiste qu'une seule colonne, un pétit pan de mur et le soubassement presque à fleur de terre; parmi les bas-reliefs subsistants, j'en ai trouvé un d'Evergète Ier. et de Bérénice sa femme; j'ai reconnu les légendes de Philopator sur la colonne, celles de Hadrien sur une partie d'architraves; et sur une autre en hiéroglyphes tout-à-fait barbares, les noms des empéreurs Antonin et Vérus." (*Lettres d'Egypte*, p. 204.)

[1] See *Lettres d'Egypte*, p. 105.

[2] Jomard, *Description de l'Egypte*, Antiq. i. c. viii. p. 9, plates 91, 96. See also Hamilton's *Egyptiaca*, p. 111. With reference to the materials with which the Egyptian temples were constructed, the author last quoted observes, "It is singular that the ancient Egyptians do not appear to have employed granite in any of the buildings in Upper Egypt, except the obelisks and some few of the propyla, as at Thebes, Elephantiné, &c. The rest are all of the common sandstone. Granite pillars seem to have been introduced so late as the time of the Christian emperors, as they are only found in the ruins of Greek churches. Their proportions and their sculpture testify the want of taste, and the decline of the arts, which characterized the age in which they were raised. In Lower Egypt, we find granite to have been in use from the earliest times; whole temples, columns, propyla, &c. were constructed exclusively of this stone, as being the only one which could resist the *frequent* and *violent* rains in the Delta, and the moisture of the air." (*Egyptiaca*, p. 112.) This is very loose and inaccurate. In Upper Egypt the nearest and most accessible materials were used; and in the Delta, though the air be moist from its proximity to the sea, the rains are neither frequent nor violent.

right there is also an inscription relative to embellishments which were executed under Ptolemy Soter II.[1] The foundation of the palace dates as far back as the commencement of the eighteenth century before Christ; but several restorations are indicated by the inscriptions, which also fix the period at which they were made. 1. All the sculptures of the upper façades south and north were executed under the reign of Rhamses-Meiamoun in the fifteenth century before our era. 2. The columns of the protodoric order which support the ceilings of the galleries were repaired under the Mendesian Pharaoh, Acoris, about four centuries before Christ. 3. The restoration of the gates, and a portion of the ceiling of the grand hall, took place under Euergetes II. between the years 146 and 118 before our era. But the principal decoration of the edifice was executed under the reigns of Thouthmosis I. Thouthmosis II. and Thouthmosis III. called Mœris by the Greek historians, particularly the last, in whose name all the dedications have been made.[2] The sculptures are executed with remarkable accuracy and with exquisite fineness of detail, and the bas-reliefs are of the very best age of the art. War and battles form the principal subjects of the hieroglyphical tablets and inscriptions.[3]

On the edge of the desert to the north and west of Medinet-Habou there are almost innumerable fragments of statues, columns, and other parts of buildings; and a quadrangular enclosure of brick walls is filled with broken remains of colossal figures and hieroglyphical tablets finely executed, whilst in a grove of mimosas or acacias similar relics of ancient sculpture occur at every step. In the plain, about half way between the desert and the river, are two statues called by some the statues of Memnon. They are about fifty feet in height, and seated each on a pedestal eighteen feet long, fourteen feet broad, and six feet high. The stone of which they are formed is a hard reddish sandstone, which, from the action of the weather, is in many places discoloured, and hence appears of a black, gray, brown, and even whitish hue. Few monuments of ancient magnificence have more interest attached to them than "Memnon's statue which at sunrise played," or at least that statue from which a certain mysterious sound was believed and reported to proceed every morning at sunrise;[4] and no question has been more keenly agitated among Egyptian antiquaries than that which relates to the identification of the statue said to have possessed this wonderful property. The French have adopted the opinion of those who regard as the vocal statue of Memnon the fallen colossus in front of the temple which they call the Memnonium. But Pococke has decided in favour of the northernmost of the two statues above described; and Mr Hamilton is inclined, on what appear to be good grounds, to prefer the opinion of our countryman. Strabo declares that the sound issued every day, resembling that of a slight blow; Pausanias agrees as to the statue uttering a sound daily at sunrise, but likens the sound uttered to that of the bursting of a string in a lyre or harp; Pliny relates the same extraordinary phenomenon, though his description of the vocal statue differs from that given by Strabo and Pausanias; and Philostratus says that it uttered a sound when the rays of the sun touched its lips.[5] In addition to these testimonies, which, from the particulars respecting the statue mentioned collaterally, seem, on the whole, to favour the opinion of Pococke, we have those of the numerous Greeks and Romans who at different times visited this statue, and engraved their names on its legs and feet, declaring that they had heard the sound or voice of Memnon at a certain hour, generally, a short time after sunrise.[6] Strabo, too, visited the statue, and heard the mysterious voice. These statues, when entire, might be seen at a distance of twelve miles, towering like solitary rocks in the midst of the plain; and the surprising length of their shadows at sunrise long rendered them an object of curiosity at that hour; but, like the kindred oracles which once inhabited the adjoining fanes, they had become mute. The hieroglyphical inscription on the throne of the vocal colossus proves that it represents Amenophis or Phamenoph II. who reigned about seventeen centuries before the commencement of the Christian era.[1]

---

[1] The change of a few stones by the Ptolemy above named is thus pompously lauded in a hieroglyphic inscription which he caused to be cut on the masonry of the right side: "This beautiful repair was executed by the king lord of the World, the grand germ of the great gods, he whom Phtah has approved, living image of Ammon-Ra, the son of the sun, Ptolemy ever-living, the god beloved of Isis, the saviour god (*soter* NT-NOHEM), in honour of his father Ammon-Ra, who has granted him the periods of the national assemblies upon the throne of Horus." The Ethiopian, who was the real founder of the pylon, has however, been content with a simple intimation of his existence. On the entablature of the gateway is sculptured this brief inscription: "King Taharaka, the well-beloved of Ammon-Ra, lord of the thrones of the world, lives." (Champollion, *Lettres d'Egypte*, p. 327.)

[2] The dedication under the gallery on the right, which is one of the best preserved, will give an idea of all the rest. It is as follows: "*First line.* Life: Horus powerful, beloved of Phré, the sovereign of the higher and the lower region, grand chief of all parts of the world, Horus resplendent, great by his force, he who has struck the nine bows (the nomadic tribes), the gracious lord of the world, the sun that gives stability to the world, the son of the sun, Thouthmosis, benefactor of the world, vivified now and for ever. *Second line.* He has caused these structures to be erected in honour of his father Ammon-Ra, king of the gods, to whom is dedicated this great temple, in the western part of the Thouthmoseion of Ammon, in beautiful sandstone; this is what the king ever-living has done." (Champollion, *Lettres*, p. 329.)

[3] Of the subjects of these battle-pieces a very correct idea may be formed from the following description of the contents of two tablets given by Champollion in the only memorial he has left of his Egyptian labours:

"1^er^ *Tableau.* Grande bataille: le héro Egyptien, debout sur un char lancé au galop, décoche des flèches contre une foule d'ennemis fuyant dans la plus grande désordre. On apperçoit sur le premier plan les chefs Egyptiens montés sur des chars, et leurs soldats entremêlés à des alliés les Fekkaro, massacrant les Robou epouvantés, ou se liant comme prisonniers de guerre. Ce tableau seul contient plus de cent figures en pied, sans compter les chevaux.

"2^e^ *Tableau.* Les princes et les chefs de l'armée Egyptienne conduisent au roi victorieux quatre colonnes de prisonniers: des scribes comptent et enregistrent le nombre des mains droites et des parties génitales coupées aux Robou morts sur le champ de bataille. L'inscription porte textuellement: 'Conduite des prisonniers en présence de sa majesté; ceux-ci sont au nombre de mille; mains coupées, trois mille; phallus, trois mille.' Le Pharaons, aux pieds duquel on dépose ces trophées, paisiblement assis sur son char, dont les chevaux son retenus par des officiers, adresse une allocution à ses guerriers; il les félicite sur leur victoire, et prodigue fort naïvement les plus grands éloges à sa propre personne…En dehors de ce curieux tableau existe une longue inscription malheureusement fort endommagée, et relative à cette campagne, qui date de l'an cinquième du règne de Rhamses-Meiamoun." (*Lettres d'Egypte*, p. 341, 342.)

[4] *Dimidio magicæ resonant ubi Memnone chordæ.* JUVENAL.

[5] Hamilton's *Egyptiaca*, p. 168, et seqq. Pococke's *Travels.*

[6] One of the numerous Greek inscriptions upon the legs and feet of the vocal colossus of Memnon has been restored as follows:

Ἔκλυον αὐδησάντος ἐγὼ Ποβλιος Βαλβίνος
Φωνὰς τὰς θειὰς Μέμνονος ἢ Φαμενωφ.
Ἦλθον ὁμοῦ ἐρατᾷ βασιλῆϊδι τῇδε Σαβίνᾳ,
Ὥρας δὲ πρώτας ἅλιος ἔσχε δρόμον
Κοιρανῳ Ἁδριανῷ πέμπτῳ δεκάτῳ ἐνιαυτῷ.
Ἅματα δ' ἔσχεν Ἄθυρ εἴκοσι καὶ πισυρα.

The history of the vocal statue of Memnon has lately been written by M. Letronne, in a paper inserted in the *Mémoires de l'Académie des Inscriptions et Belles-Lettres*, new series, tom. x. "Ce sujet, curieux seulement en apparence, est devenu, sous la plume de M. Letronne, l'un des plus piquants et des plus utiles à étudier dans la recherche des rapports et du mélange des opinions de la Grèce avec celles de l'Egypte." (*Lettres*, ubi supra.)

Between Medinet-Habou and El-ebek or Kournah there is another mass of ruins as stupendous in their dimensions as they are admirable in their execution. They have been supposed by some to mark the site of the Memnonium, probably on account of the broken colossal statue of red granite which lies overturned within their precincts, while, according to others, they are the remains of the tomb of Osymandyas, the mighty conqueror whose sepulchre was to surpass every thing upon earth.[2] This last denomination originated with the French Egyptian Commission; and several travellers still persist in employing that of the Memnonium, which is equally ill applied and incorrect. The real name of the structure whose ruins yet attest its stupendous magnificence is, the Rhamesseion, so called from Rhamses the Great, to whom Thebes was indebted for the edifice; and this name, accordingly, is found sculptured in a hundred places, and repeated in the legends of the friezes, architraves, and bas-reliefs, which decorate the palace. "L'imagination s'ébranle," says Champollion, "et l'on éprouve émotion bien naturelle en visitant ces galeries mutilées et ces belles colonnades, lorsqu'on pense qu'elles sont l'ouvrage et furent souvent l'habitation du plus célèbre et du meilleur des princes que la vieille Egypte compte dans ses longues annales."[3] No part of the Rhamesseion remains entire; but what has escaped the barbarism of the Persians and the ravages of time is sufficient to give a pretty exact idea of the whole. Within the walls, which inclose a space of more than two hundred feet in breadth by six hundred in depth, the whole area is a forest of pillars, interspersed with fragments and fallen statues. The body of the palace was approached by a noble propylon, fronting the fertile plain, and resting upon it; but the remainder of the edifice rests on the adjoining mountain, the rock of which has been levelled to form the floor. In the propylon there are passages leading to several chambers and to the roof; and this propylon is separated from the first wall of the palace by a distance of a hundred and sixty feet. In the court behind the propylon are the fragments of the enormous statue already alluded to. It has been broken off at the waist, and the upper part is now laid prostrate on the ground. This enormous statue measures sixty-three feet round the shoulders, thirteen feet from the crown of the head to the top of the shoulders, thirteen and a half from the shoulder to the elbow, and nearly seven feet over the foot. The face has been so entirely obliterated that nothing even of its general expression can now be discerned. "Next to the wonder excited by the boldness of the sculptor who made it," says Mr Hamilton, "and the extraordinary powers of those who erected it, the labour and exertions that must have been used for its destruction are most astonishing."[4] The court which intervenes between the statue and the opposite quarter is about a hundred feet in width. Four square columns formerly stood on the opposite side of the door-way, making a row of eight, which faced a like number, some of which are still to be seen. Two sides of the court were bounded by a double row of enormous pillars, parts of the capitals of which, thirty-two feet in circumference, yet remain; and behind the square columns there were others of a similar description; so that, when the whole was roofed, it must have been a truly magnificent piazza. The fronts of the square columns have been carved into statues in full relief, measuring twenty feet to the shoulder; and below the figures, which are all shaped like a soros, are rows of hieroglyphics. The pillars form the ruins of a central hall, the roof of which was supported by forty-eight columns; beyond this is a second hall entered by a door-way, and divided from the other by a cross wall; and the remains of a third, which are seen farther on, terminate the magnificent ruins of the Rhamesseion. The side walls which inclose this edifice have been removed, and many columns and statues have been destroyed; but the remnants, which have escaped all sorts of ravages, are sufficient to awaken boundless admiration of the power as well as genius which presided in the construetion of the mighty fabric.[5] The architecture throughout is perhaps in the purest and noblest style of any at Thebes. It would be endless to attempt any detailed description of the hieroglyphics, pictorial tablets, and bas-reliefs of this wonderful monument. They relate principally to the achievements and conquests of Sesostris, and the adoration of the gods of Thebes by that mighty potentate. The following is the dedication of the great hall, sculptured in name of the founder, in beautiful hieroglyphics, upon the architraves of the left side: "Haroëris all powerful, the friend of truth, the lord of the upper and lower regions, the defender of Egypt, the castigator of foreign countries, Horus the resplendent possessor of the palms, the greatest of conquerors, the king-lord of the World, sun guardian of justice approved by Phré, the son of the sun, the well-beloved of Ammon, RHAMSES, has caused these structures to be erected in honour of his father Ammon-Ra, king of the gods: he has caused to be constructed, in good white sandstone, the Great Hall of Assembly, supported by large columns with capitals imitating full-blown flowers, and flanked by smaller pillars with capitals imitating a truncated bud of the lotus; and he has dedicated the Hall to the lord of gods, for the celebration of his assemblies; this is what the king ever living has done."[6]

---

[1] A large temple, and a great number of fine statues, have since been discovered near the same spot in the course of the excavations which were made under the direction of Mr Salt and other recent travellers in Egypt.

[2] Diodorus Siculus, i. 47.

[3] *Lettres écrites d'Egypte et de Nubie*, p. 261.

[4] *Egyptiaca*, p. 167, 168. Mr Hamilton adds, "Its fall has carried along with it the whole wall of the temple [palace] which stood within its reach. It was not without great difficulty and danger that we could climb on its shoulder and neck; and in going down from thence on its chest I was assisted by my Arab servant, who walked by my side in the hieroglyphic characters engraven on the arm."

[5] Captain Head's *Eastern and Egyptian Scenery, Ruins, &c.* p. 22. The excellent lithograph view of the Rhamesseion given in this work was taken from the back of the prostrate colossus. There also remain the fragments of a statue of black granite, represented in Captain Head's plate, which has been absurdly styled the brother of the younger Memnon, which Mr Belzoni conveyed hence to England, and placed in the British Museum. Like its exported companion, it has a benignant expression of countenance, with the full Ethiopian expansion of nostril and lip by which the sphinxes in the neighbourhood are characterized. The features are somewhat elongated, but remarkably regular. For an account of Mr Belzoni's achievement, see *Researches and Operations*, p. 40, et seqq.

[6] Champollion, *Lettres écrites d'Egypte*, p. 273. In concluding his observations on this wonderful ruin, Champollion observes, "Le Rhamesseion est le monument de Thèbes le plus degradé, mais c'est aussi, sans aucune doute, celui qui, par l'élégante majesté de ses ruines, laisse dans l'esprit des voyageurs une impression plus profonde et plus durable." P. 291.

Having shown by the legends and other evidence that the magnificent ruin which has been considered by some as the remains of the Memnonium, and by others as those of the Tomb of Osymandyas, is in reality the wreck of the Rhamesseion, we shall now endeavour to ascertain the exact site of that celebrated edifice of Thebes called Amenophion by the Egyptians, but known among the Greeks by the name of the Memnonium. And here we may observe, that if what has been stated above respecting the statue of Memnon, or of Amenophis the third of that name, whom the Greeks call Memnon, be well founded, the position occupied by this and the corresponding colossus must in some measure determine the site of the Memnonium. Accordingly, the legends discovered on the ruins scattered about, such as the débris of architraves, portions of colossal figures, shafts of columns, and fragments of enormous bas-reliefs, together with the hieroglyphical inscriptions found in the *hypogœa* of the neighbourhood, which contained the mummies of the great officers charged, during their lifetime, with the guardianship of this edifice, all lead to the same conclusion which Jollois and Devilliers, in their excellent description of these ruins, had arrived at from other considerations; namely, that the ruins towards the extremity of which, on the side of the river, appear the two enormous monolith statues, about sixty feet in height, commanding the whole plain of Thebes, mark out the site of the Amenophion or Memnonium. These two figures, which are formed each of a single block of grey breccia, transported from the quarries of the upper Thebaid, and placed in a sitting posture on immense bases of the same material, with the hands extended on the knees in an attitude of repose, seem to have decorated the exterior façade of the principal pylon of the Amenophion; and, in an inscription on the seat of one of the figures, we find the names and titles of the third Amenophis of the eighteenth dynasty, called Memnon by the Greeks, who occupied the throne of the Pharaohs in the seventeenth century before the Christian era, most distinctly and accurately enumerated. The following is the concluding portion of this legend: "The lord sovereign of the upper and lower region, the reformer of manners, he who holds the world in repose, Horus, who, great by his power, has smitten the barbarians, the king sun lord of truth, the son of the sun, AMENOTHPH, moderator of the pure region, beloved of Ammon-Ra, king of the gods." The dedication of this palace, which is altogether dramatic, being in the form of a dialogue between Amenoph or Amenothph and Ammon-Ra, "king of the gods," is entirely in accordance with the inscription of which we have here quoted a part: the king appears in the character of founder of the edifice, and the Jupiter of the Egyptian Pantheon thus responds to the invocation of his representative upon earth: "Approach, my son, sun lord of truth, of the germ of the sun, son of the sun, *Amenothph;* I have heard thy words, and I perceive the structure which thou hast executed; I who am thy father rejoice in beholding thy good works." The identity of the Memnonium of the Greeks and the Amenophion of the Egyptians is therefore no longer doubtful; and it is still less so, that "when the Memnonium was in all its glory," it formed one of the greatest wonders of the old capital of Egypt.[1]

Situated behind the Amenophion, in a valley formed by the rocks of the Libyan mountain and a large mamelon detached from them on the side of the plain, is a small temple in a state of perfect preservation, which the French Egyptian Commission has described under the name of the Little Temple of Isis. It is entered by a small propylon of sandstone attached to the enceinte, and covered on the exterior side with sculptures heavily elaborated. Its situation is dreary and dismal. The tablets upon the bandeau of the gateway represent on the one side Ptolemy Soter II. presenting offerings to Hathôr and the great triad of Thebes, Ammon-Ra, Mouth, and Chons; and on the other, the goddess Thmé or Themeï (Themis), and a triad formed of the hieracocephalous god Mandou, his wife Ritho, and their son Harphré. The temple was therefore dedicated to Hathôr or Venus, identified with Themeï or Themis; in other words, the principle of beauty was here worshipped mythologically in conjunction with that of truth and justice. This is completely confirmed by the hieroglyphical inscription sculptured along the frieze of the pronaos, part of which has been translated by M. Champollion. The naos is divided into three contiguous halls, forming as many sanctuaries, the principal of which, being that in the middle, is entirely covered with sculptures of an import similar to those already described. The sanctuary on the left was consecrated to Themeï, and all the tablets with which it is decorated relate to the functions performed by that goddess in Amenti, or the Egyptian Tartarus.[2]

The palace of Kournah, though also of small dimensions compared with the great and important edifices we have described, is nevertheless an interesting monument, as it belongs to the Pharaonic times, and dates from the most glorious epoch in the annals of ancient Egypt. Besides, its appearance presents a character altogether new; and if its general plan suggests the idea of a private habitation, and seems to exclude that of a temple, the magnificence of the decoration, the profusion of the sculptures, the beauty of the materials, and the perfection of the execution, prove that this habitation formerly belonged to a rich and powerful sovereign. The remains of this palace occupy only the extremity of an artificial mound or bank of earth, on which there were formerly other structures connected with that which still exists; at least all the fragments scattered over the ground bear royal names belonging either to the last Pharaohs of the eighteenth or the first of the nineteenth dynasty. In the same line with these remains rises a portico a hundred and fifty feet in length and thirty in height, supported by ten columns, whose shafts are composed of wreaths of lotus-stems, whilst the capitals are formed of buds and flowers of the same plant, truncated so as to admit the coping. On the four faces of the capitals are sculptured with much care the royal legends of Menephtha I. and also those of Rhamses the Great; and the names of these Pharaohs are likewise inscribed on the shafts of the columns, but joined together and included in a square tablet. The dedicatory legend which adorns the architrave of the portico, occupying its whole length, establishes two principal facts; first, that the palace of Kournah was founded and erected by Menephtha I.; and, secondly, that his son Rhamses the Great, having completed the decoration of the edifice, surrounded it with an enceinte ornamented with propylons, and similar to that within which each of the great royal monuments at Thebes is contained. In fact, all the bas-reliefs which decorate the interior of the portico, and the exterior of the three gates which lead to the apartments of the Menephtheion, represent Menephtha I. and more frequently still Rhamses the Great, rendering homage to the Theban triad and to the other divinities of Egypt, or receiving from the munificence of the gods royal powers and precious gifts in order to embellish and prolong life. And the only sculptures of the edifice posterior to the time of Rhamses the Great consist of some royal onomastic inscriptions, placed either on the sides or basement of the gates, but wholly unconnected with the primitive decoration; all of them, with the exception of one which contains the names and titles of Rhamses-Meiamoun, belonging to the reign of Menephtha II. the son and immediate successor of Rhamses the Great.[1]

---

[1] Champollion, *Lettres écrites d'Egypte et de Nubie*, p. 303, et seqq. Among the ruins of the Amenophion, on the side of the Libyan mountains, on the border of the desert, are two blocks of grey breccia, each about thirty feet in length, which exhibit the form of enormous *stelæ* or pillars, and are covered with hieroglyphical tablets, which, according to Champollion, "nous montrent toujours le roi *Amenophis-Memnon*, accompagné ici de la reine Taïa son épouse, accuillis par le dieu Amon-Ra, ou par Phtah-Socharis." P. 309.

[2] The two sovereigns of this terrible place (where, according to the Egyptian mythology, the souls of men were judged), Osiris and Isis, receive at first the homage of Ptolemy and Arsinoë, gods Philopators; and on a cross or partition wall is sculptured the grand scene of the psychostasis. This vast bas-relief represents the hypostyle hall called in Egyptian *Oskh*, or the court of Amenti, with suitable decorations. The grand judge, Osiris, occupies the further extremity of the judgment-hall; and at the foot of his throne appears the lotus, the emblem of the material world, surmounted with images of his four children, the directing genii of the four winds or cardinal points. The forty-two judges, assessors of Osiris, are ranged in a double line, each having his head surmounted with an ostrich feather, the symbol of justice; whilst, on a bench before the throne, the Egyptian Cerberus, or *Teouôm-enement*, a triple monster, at once crocodile, lion, and hippopotamus, opens his horrid jaws, ready to devour guilty souls. Towards the door of the tribunal appears the goddess Thmeï redoubled, or twice represented, by reason of her twofold function of goddess of truth as well as of justice; and the first form, qualified as Thmeï, ruler of Amenti (truth), presents the soul of an Egyptian, under a corporeal form, to the second personation of the goddess (justice), whose legend is as follows: "Thmeï, who resides in Amenti, where she weighs the hearts of all men in a balance, and whom the wicked cannot escape." In the neighbourhood of him who is here undergoing his final trial are the words, "arrival of a soul in Amenti;" and further on is an infernal balance, into the scales of which Horus, the hawk-headed son of Isis, and Anubis the shakal-headed son of Osiris, are placing, the one the heart of the arraigned, and the other a feather, the emblem of justice; whilst, between the fatal instrument which is to decide the fate of the soul, and the throne of Osiris, is placed the biocephalous god Thoth, described as "thrice great, the lord of Schmoun (*Hermopolis Magna*), the lord of the divine words, the secretary of justice to the other gods in the hall of justice and of truth." This divine recorder writes the result of the trial to which the heart of the deceased Egyptian has just been subjected, and goes to present his report to the sovereign judge who presides in Hades. (Champollion, *Lettres écrites d'Egypte*, pp. 319, 320.)

The catacombs in the western mountains are not less abundant than the monuments we have described, in treasures illustrative of the ancient history of Egypt. In the valley of Biban-el-Molouk, a rocky ravine to the south-west of Kournah, are the sepulchres of the kings of the three Diospolitan or Theban dynasties, being the eighteenth, nineteenth, and twentieth.[2] The site chosen for the royal necropolis appears to be eminently suited to its melancholy destination; for a valley or ravine, encased, as it were, by high precipitous rocks, or by mountains in a state of decomposition, presenting large fissures, occasioned either by the extreme heat or by internal sinking down, and the backs of which are covered with black bands or patches, as if they had been in part burned, is a spot which, from its loneliness, desolation, and apparent decay, harmonizes well with our ideas as to the most fitting locality for a place of tombs. No living animal, it is said, frequents this valley of the dead; even the fox, the wolf, and the hyena shun its mournful precincts; and its doleful echoes are only awakened at intervals by the foot of the solitary antiquary, led by inquisitive curiosity to pry into the very secrets of the grave. The catacombs or *hypogœa* are all constructed on nearly the same plan, yet no two of them are exactly alike: some are complete, others appear never to have been finished, and they vary much in the depth to which they have been excavated. In general, the entrance is by the exterior opening of a passage twenty feet wide, which descends gradually about fifty paces, then expands whilst the descent becomes more rapid, and is continued for some distance farther. On either side of this passage is a horizontal gallery, on a level with the lowest part of the first descent; small chambers also branch off sides of the second descent; at the interior extremity there is a spacious and lofty apartment, in the centre of which is placed the royal tomb; and beyond this there are commonly other small chambers at the sides, whilst in some cases the principal passage is continued a long way into the rock. The royal tomb is for the most part a sarcophagus of red or grey granite, circular at the one end and square at the other; but where there is no sarcophagus a hole or grave is discovered, cut in the rock to the depth of from six to thirty feet, and which appears to have been covered by a granite lid. Almost all the lids, however, belonging to the graves excavated in the rock, have either been removed or broken. In those sepulchres which have been finished, the walls from one end to the other are all covered with sculptures and paintings executed in the best style of ancient art; and, owing to the unparalleled dryness of the atmosphere in Egypt, the colours, where they have not been purposely damaged,

---

[1] Champollion, *Lettres*, 380, et seqq. It may perhaps conduce to perspicuity, or at least serve to prevent mistakes, if we introduce here the eight reigns anterior to that of Rhamses-Meiamoun, in their chronological order. They stand thus: 1. Amenophis II. or Memnon; 2. Horus; 3. Rhamses I.; 4. Menephtha 1. or Ousireï; 5. Rhamses the Great, or Sesostris; 6. Menephtha II.; 7. Menephtha III.; 8. Rhamerreh; and, 9. Rhamses-Meiamoun. The monuments of different orders having clearly demonstrated that Rhamses the Great, the Sesostris of Herodotus, must be included in the eighteenth dynasty, as answering exactly to the Rhamses called *Ægyptus* in the extracts of Manetho, it follows that in Rhamses-Meiamoun, the Rhamses-Sethos of the same lists of Manetho, we recognise the head or chief of the nineteenth dynasty.

[2] The following is Manetho's catalogue of the Diospolitan dynasties and kings.

XVIII. Dynasty. Diospolitan.

		Years.	B. C.
1.	Thouthmosis or Amosis, reigned	24	1874
2.	Chebron his son	13	1750
3.	Amenophthis	20	1737
4.	Ammosis, sister	18	1717
5.	Mesphres, son	16	1699
6.	Misphragmuthosis	23	1683
7.	Thmosis or Thouthmosis, s.	9	1660
8.	Amenophis, s. (Memnon)	31	1651
9.	Horus, s.	41	1620
10.	Acenchres, d.	23	1579
11.	Rathotis, sist.	15	1556
12.	Acencheres, s.	17	1541
13.	Acencheres II. s.	11	1524
14.	Armais	6	1513
15.	Ramesses or Rhamses s.	68	1507
16.	Armesses Meiamoun, s.		
17.	Amenophis or Amenophth	15	1439

XIX. Dynasty. Diospolitan.

		Years.	B. C.
18.	Rhamses the Great or Sesostris	53	1424
19.	Rapasces	63	1371
20.	Ammenophthes	60	1308
21.	Rameses or Rhamses		
22.	Ammenemes	15	1248
23.	Thuoris	7	1233

XX. Dynasty. Diospolitan.

		Years.	B. C.
24...35.	Twelve kings	125	1226

are as fresh as when first laid on.[1] The labours of Belzoni in exploring these tombs, and the success with which they were rewarded, are well known. Strength and resolution as herculean and inflexible as his were required to overcome the suspicions of the Arabs, the want of mechanical aid, and the heat and closeness of the caverns; but his perseverance was amply recompensed by the discovery of six tombs in this hypogean city of the dead. The most remarkable of these, with all its galleries, is upwards of three hundred feet in length, and is called by Belzoni the tomb of Apis, from his having found the mummy of a bullock in one of its chambers. In another apartment there was a magnificent sarcophagus of white alabaster, almost as transparent as crystal; and the whole excavation, sculptured and painted in the most finished style of art, was in the most perfect preservation.[2] These catacombs, as already stated, were the sepulchres of the kings of the three Diospolitan dynasties; and accordingly, by means of the hieroglyphical inscriptions, Champollion discovered the tombs of six kings of the eighteenth dynasty; that of Amenophis-Memnon, the most ancient of all, in an isolated part of the valley towards the west; and, lastly, those of Rhamses-Meiamoun, and six other Pharaohs, his successors, belonging either to the nineteenth or the twentieth dynasty. No sort of order, either in regard to dynasty or succession, appears to have been observed in the choice of situations for the different royal tombs; on the contrary, each sovereign seems to have caused his own to be dug wherever he found a vein of stone adapted for the purposes of sepulture and the immensity of the projected excavation. The royal catacombs, however, which have been thoroughly completed and finished are but few in number: these are, the tomb of Amenophis III. or Memnon, the decoration of which has been almost entirely destroyed; that of Rhamses-Meiamoun, that of Rhamses V., probably also that of Rhamses the Great, and, lastly, that of Queen Thaoser. All the others are incomplete. The tomb of the great Rhamses or Sesostris still exists, according to M. Champollion, and is the third on the right of the principal valley; but it has sustained greater injury than almost any others, and is filled nearly to the ceiling with rubbish. That of Rhamses V. is remarkable for a large tablet and an inscription on a cross wall in the apartment at the further extremity of the catacomb, containing images or delineations of the forty-two assessors of Osiris, intermixed with justifications which the king is supposed to offer to these severe judges, each of whom appears to be charged with investigating a particular offence or sin, and with punishing it in the soul of the sovereign subjected to their jurisdiction. The royal justification amounts merely to a negative confession, which, whatever may have been its effect in the Egyptian Amenti or Hades, would, in judging kings, certainly go a great way upon earth. It is somewhat in this strain: The son of the son Rhamses has *not* been guilty of great iniquities; he has *not* blasphemed; he has *not* been a drunkard; he has *not* been indolent or lazy; he has *not* seized upon the offerings devoted to the gods; he has *not* told falsehoods; he has *not* been a libertine; he has *not* stained himself with impurities; he has *not* hung down his head when hearing the words of truth; he has *not* been prolix in his talk; he has *not* had to devour his heart, or, in other words, to repent of any wicked action; and so on through the remaining thirty-one negations.[3]

Having thus described the Diospolitan monuments on the western bank of the Nile, we now turn to the still grander and more magnificent remains with which the eastern bank of the river is adorned. No people, ancient or modern, can boast of an architecture approaching in magnitude and sublimity, not to mention elaborate decoration, to that of the old Egyptians, who conceived men a hundred feet in height, and not only planned, but erected temples and palaces larger than some modern cities. In Europe the imagination is easily transported beyond the dimensions of our proudest and most magnificent porticoes, and it can readily conceive something of the kind upon a still grander scale; but in Egypt it sinks abashed, overawed, and powerless at the base of the hundred and forty columns of the hypostyle hall of Karnak. The first sight of the wonderful structures on the right bank arrested the march of the French army; the troops, suddenly overpowered with awe and wonder, stood motionless, and it was only after a time that they could whisper to each other, "This is Thebes."[4] The monuments on the eastern bank of the Nile are the palace of Luxor and the temple of Karnak.

In approaching the palace of the Pharaohs from the north, the first object which meets the view is a magnificent propylon or gateway two hundred feet in length, the top of which is elevated about sixty feet above the present level of the soil. And in front of this entrance are the most perfect obelisks in the world, each formed of a single block of red granite from the quarries of Elephantiné: they are between seven and eight feet square at the base, and about eighty feet in height, and many of the hieroglyphical figures with which they are covered are cut an inch and three quarters deep, exhibiting at the same time the greatest nicety and precision of execution. Between these obelisks and the propylon are two colossal statues, also of red granite, measuring forty-four feet from the ground, and supposed, from the difference of the dresses, to have been, the one a figure of a male, and the other that of a female. Another propylon of similar proportions guards another approach, and from both gateways magnificent peristyles lead to the main body of this palace of the Pharaohs. Some of the columns of the peristyles are eleven feet in diameter. The sculptures on the pylons, like those at Medinet-Habou, represent the victories of Sesostris, with the greatest amplitude of detail. "It was impossible," says Mr Hamilton, "to view and to reflect upon a picture so copious and detailed, without fancying that I here saw the original of many of Homer's battles, the portrait of some of the historical narratives of Herodotus, and one of the principal ground-works of the narratives of Diodorus; and, to complete the gratification, we felt that, had the artist been better acquainted with the rules and use of perspective, the performance might have done credit to the genius of a Michael Angelo or a Julio Romano." In regard to the general plan of the palace and its environs, as well as the distribution of the entrances and of the interior of the building, the delineations of Pococke and Denon, to which may be added those contained in Captain Head's work, will serve to convey a more distinct and accurate idea of the magnificent design than can be communicated by any verbal description. "But without personally inspecting this extraordinary edifice," says Mr Hamilton, "it is impossible to have any adequate notion of its immense size, or of the prodigious masses of which it consists. In both these respects, and, combined with them, in respect to the beauty and magnificence of its several parts, it is, I should imagine, unique in the whole world."[1] The founder of this marvellous palace is conjectured, from the inscriptions, to have been Amenophis-Memnon, or Amenophth III., who is supposed to have erected the series of edifices extending south and north from the Nile as far as the fourteen columns of forty-five feet in height, which also belong to the same reign. The dedication by this Pharaoh may be read on all the architraves of the columns, a hundred and five in number, and for the most part entire, which adorn the courts and inner halls. The bas-reliefs which decorate the palace of Amenophis relate chiefly to the religious acts performed by that prince in honour of the divinities of this portion of Thebes; namely, Ammon-Ra, Ammon-Ra-Generator, his secondary form, the goddess Tamoun, one of the forms of Neïth, the goddess Mouth, companion of Ammon-Ra, and the young gods Khons and Harké, the two great triads adored at Thebes. The two obelisks of red granite in front of the northern pylon were erected by Sesostris in order to decorate his Rhamesseion. This is proved by the hieroglyphic inscription on the obelisk on the left, which is in these terms: "The lord of the world, sun guardian of truth (or justice), approved by Phré, has caused this edifice to be built in honour of his father Ammon-Ra, and has also erected these two great obelisks of stone before the Rhamesseion of the city of Ammon."[2]

[2] Belzoni, *Researches and Operations*, p. 123 and 224, et seqq. Mr Salt observes that the colours are generally pure and brilliant, but intermixed with each other nearly in the proportions of the rainbow, and so subdued by the proper introduction of blacks as not to appear gaudy, but to produce a harmony that in some of the designs is really delicious. "One would think it was in Egypt," says Mr Bechey, "that Titian, Giorgione, and Tintoret, had acquired all that vigour and magic of effect which distinguishes them so remarkably from all other painters in point of arrangement, and principally in the happy disposition of their darks." (Young, *View of the latest Publications relating to Egypt*.)

[4] Napoleon's *Memoirs*, vol. ii. Denon's *Travels in Egypt*.

The palace at Luxor communicates with the temple at Karnak, an edifice not less Titanian in its dimensions, nor less marvellous in its structure. This temple has twelve principal entrances, each of which is composed of several propyla or colossal gateways, besides other buildings attached to them larger than most temples. The sides of some of these gateways are equal in dimensions to the bases of the greater part of the pyramids in the Heptanomis, and they are built in the same style, each layer of stone projecting a little beyond that immediately above it. One of the propyla is built entirely of granite, and adorned with hieroglyphics of the most finished execution; and on each side of several of these there have been colossal statues of basalt, breccia, and granite, some in a sitting posture, some erect, and varying from twenty to thirty feet in height. Avenues of sphinxes lead in several directions to the propyla, and correspond to the magnificence which they promise. The principal of these, continued across the plain to the palace at Luxor, establishes a communication to which there is no parallel upon earth.[3] For the space of nearly a mile and a quarter (1026 toises, or about 6200 feet), a broad raised causeway, bordered by more than six hundred colossal sphinxes, representing lions with rams' heads, leads from the one edifice to the other; and another similar road, branching off from this, passed between figures of rams on lofty pedestals to a triumphal gateway leading to a temple, apparently the most ancient in Thebes. "On approaching the avenue of sphinxes which leads to the great temple, the visitor," says Belzoni, "is inspired with devotion and piety; their enormous size strikes him with wonder, and respect for the gods to whom they were dedicated."[4] The body of the temple, which is preceded by a large court, at the sides of which are colonnades of thirty columns in length, and through the middle two rows of columns fifty feet in height, consists principally of a grand hypostyle hall or portico, the roof of which is supported by a hundred and thirty-four columns, some of them twenty-six and others thirty-four feet in circumference; and four beautiful obelisks mark the entrance to the adytum or sanctuary, near which the sovereign of the gods is represented as embraced by Isis. The adytum itself consists of three apartments, formed entirely of granite. The part of the edifice at which the branch of the avenue of sphinxes terminates is the most surprising of all amongst these astonishing monuments. From most points of view it appears a boundless, confused wreck of splendid buildings, scattered in every direction, without any perceptible order or design; but, when viewed from the north-west end of the principal group, the whole may be surveyed by the eye at once, and the extraordinary dimensions and magnificence of the great entrance from the west in some measure appreciated. An unfinished pylon, succeeded by an avenue of columns more than seventy-five feet in height, all of one block, but only one of them standing; a second pylon, leading to a hall three hundred and thirty-eight feet in length by a hundred and sixty-eight feet in breadth; a third pylon, opening into a court in which there are two obelisks more than seventy-two feet in height; and a fourth pylon, leading to a court in which is the largest obelisk ever formed of one stone; all these magnificent objects are seen following exactly in the same line, and forming a perspective, the effect of which cannot be conveyed by any drawing, much less by any description. The great obelisk is nearly a hundred feet in height, and, as already stated, is formed of a single block.[5] The walls are everywhere covered with hieroglyphics or sculptures representing the battles, triumphs, sacrifices, processions, and festivals of the ancient Egyptians; and the colours with which they were decorated are still, in many places, extremely fresh and vivid. On the northern side of these gigantic edifices there were also triumphal arches, colonnades, sphinxes, and other monuments of Egyptian art and magnificence in vast numbers; but they have also suffered more or less from the ravages of fanatical invaders, or the slower but not less certain havoc committed by naturalized barbarians. On the great dwelling of Ammon,

[2] Champollion, *Lettres écrites d'Egypte*, p. 215. In a letter dated from Thebes, Champollion, speaking of the Egyptian architecture, observes: "It is evident to me, as it must be to all who have examined Egypt, or have an accurate knowledge of the Egyptian monuments existing in Europe, that the arts commenced in Greece by a servile imitation of the arts in Egypt, much more advanced than is commonly believed, at the period at which the first Egyptian colonies came in contact with the inhabitants of Attica or the Peloponnesus. Without Egypt, Greece would probably never have become the classical land of the fine arts; such at least is my belief touching this great problem. I write these lines almost in presence of bas-reliefs which the Egyptians executed with the most refined elegance of workmanship seventeen hundred years before the Christian era. What were the Greeks doing then?"

[3] Hamilton's *Egyptiaca*, p. 122.

[4] *Researches and Operations in Egypt and Nubia*, p. 152. From the ruins within the area of the ancient temple ascribed to Osymandyas, Belzoni recovered many fine specimens of Egyptian art, which are now in the British Museum, and amongst these a statue which is supposed by some to represent that great conqueror, in other words, Sesostris.

[5] *Encyclopædia Metropolitana*, art. *Egypt*.

Champollion observed real portraits of most of the old Pharaohs renowned for their great actions, each with his appropriate physiognomy, and therefore distinguishable from the others. In the colossal tablets, which are as finished in execution as they are heroic in design, may be seen Mandoueï combating the enemies of Egypt, and returning in triumph to his native country; the campaigns of Rhamses the Great are also represented with much fulness of detail; and Sesonchis may likewise be observed dragging to the feet of the Theban trinity (Ammon, Mouth, and Khons) the chiefs of more than thirty conquered nations, including amongst the last the Israelites or Jews. One of the bas-reliefs, representing Judah personified, contains, in hieroglyphic characters, the IUDAHAMELEK, "the kingdom of the Jews, or of Judah," and thus forms a sort of commentary to the fourteenth chapter of the second book of Kings, which records the arrival of Sesonchis at Jerusalem, and the success of that invader, at the same time establishing the identity of the Egyptian Scheschonk, the Sesonchis of Manetho, and the Sesak or Scheschôk of Scripture. This, it will be admitted, is a very remarkable and interesting discovery.[1]

That the magnificent ruins of Medinet-Habou, Luxor, and Karnak, are the remains of the Thebes described by Homer, the earliest capital of the world,

> That spread her conquests o'er a thousand states,
> And poured her heroes through a hundred gates,

cannot possibly be doubted. According to the admeasurement made by the French, the distance of these ruins from the sea amounts to eight hundred and fifty miles, and from Elephantiné two hundred and twenty-five, thus corresponding pretty exactly with the 6800 and 1800 stadia respectively mentioned by Herodotus. Exclusively of the hippodrome and of Medamoud, the circumference of the ruins is from fourteen to fifteen thousand mètres, which agrees with the 140 stadia, or seventeen miles and a half, mentioned by Diodorus Siculus as the circumference of the ancient capital of Egypt. The origin of the name of this celebrated city, as well as the date of its foundation, is unknown. It has been conjectured, however, that the word *Thebæ* is derived from the Egyptian word *Thbaki*, signifying "the city;" and hence the *Diospolis* of the Greeks is, in this view, a mere translation of the Thbaki-antepi-Amoun, or the city of Ammon the most high god. The No-Ammon of the Hebrews, though identical in import with the Greek name, applies not to *Diospolis Magna*, but to *Diospolis Parva*, in the Delta.[2]

Kous, called Kous-birbir by the Egyptians, occupies the site of the *Apollonopolis Parva* of the Greeks. Of its ancient edifices there exists only a propylon, half buried in the sand. This propylon was dedicated to the god Aroëris; and his images, sculptured on all the faces, are adored on that which looks towards the Nile, being the principal one. The upper face towards the temple is covered with sculptures, amongst which may be discovered the royal legends of Ptolemy-Alexander I., who also takes the surname of Philometor. With respect to the Greek inscription, the restitution of ΣΩΤΗΡΕΣ, at the commencement of the second line, proposed by M. Letronne, is undoubtedly right; but the proposed substitution of ΗΛΙΩΙ for ΑΡΩΗΡΕΙ is not equally fortunate, the words ΑΡΩΗΡΕΙ-ΘΕΩΙ being still distinctly legible.[3] At Keft, Kebt, or Coptos, which, like Kous, is near an opening into the valley of Cosseir, nothing remains entire. The temples were demolished by the Christians, and the materials employed in building a large church, in the ruins of which may be found numerous portions of Egyptian bas-reliefs. Amongst the royal legends were recognised those of King Nectanebo, and of the Emperors Augustus, Claudius, and Trajan; from which it may be inferred that the city of Coptos contained few monuments of high antiquity. It is first mentioned in history under the Ptolemies; it attained its greatest prosperity in the time of Strabo; it began to decline about the beginning of the eleventh century; it was greatly reduced in the fourteenth, and is now a wretched Arab village, distinguished only by the remains which we have mentioned.[4] Kenneh or Ghenneh[5] has now succeeded Keft and Kous as the entrepôt for the Arabian and Indian commerce with Egypt, and it is the place where all the caravans and pilgrims travelling eastward usually assemble.

Opposite to Kenneh is the village of Denderah, on the left bank of the Nile, surrounded by groves of date, palms, and domms; the latter of which is seldom or never seen farther northward. About a mile and a half to the east of this village lie the ruins of *Tentyris*, occupying an area of more than a mile in length, about half a mile in breadth, and rather more than two miles and a half in circumference. Amidst the high mounds and dilapidated walls of this ancient city are the remains of a small hypæthral temple, about sixty feet square, consisting of twelve columns placed at the sides, and connected by a wall reaching to within sixteen feet of their capitals, but entirely free from hieroglyphical sculptures, and with capitals which in form approach to those of the old Tuscan order. The entrances, two in number, are in a line with the other approaches to the great temple, and seem to mark out this small edifice as having formed one of its appendages. At a short distance from the building in question is the principal propylon of the great temple, that magnificent edifice which has rendered Denderah so long famous among the cities of Egypt. This propylon is one of the most perfect models of Egyptian architecture; and, notwithstanding one side has in part fallen down, it still retains the true Egyptian character of grandeur and simplicity.[6] "Je n'essaierai pas

---

[1] Champollion, *Lettres*, p. 99. According to the Bible, Sesonchis attacked and took Jerusalem in the fifth year of the reign of Rehoboam; and it is this victory, accordingly, which the bas-relief of Karnak commemorates. The personification of the kingdom of Judah represents the physiognomy of the Jewish people, as it was conceived by the Egyptians in the tenth century before our era; and it is not impossible that Rehoboam himself may have sat for the portrait. The hieroglyphic legend which fixes the character of the tablet is given on the margin. The personification we have been obliged to omit; it appears, however, to have been executed with that fidelity of physiognomy which is remarkable in all the ancient Egyptian works of art referable to the foreign nations whom they have represented on their monuments. Upon the whole, if this discovery be taken in connection with others, particularly the delineations of captive Jews found by Belzoni in the catacombs of Biban-el-Molouk, and the deciphering of the name of Tirhakah king of Ethiopia by Mr Salt, it will not be disputed that Scripture history may receive illustrative confirmation from the study of Egyptian antiquities.

de décrire l'impression," says Champollion, " que nous fit le grand propylon et surtout le portique du grand temple. On peut bien le mesurer, mais en donner une idée c'est impossible. C'est la grace et la majesté reunies au plus haut degré."[1] The height of this gateway is forty-two feet, the width thirty-three, and the depth seventeen; each front, as well as the interior, is covered with sculpture beautifully executed;[2] and upon its roof was the celebrated planisphere now at Paris, and so long the subject of extravagant speculations connected with the chronology of Egypt. For some reason, whether arising from war, revolution, or deficiency of money, the flanks have been left unfinished. The portico, which so particularly attracted the admiration of Champollion, and is indeed most beautiful, consists of twenty-four columns, disposed in three rows, each being above twenty-two feet in circumference, thirty-two in height, and covered with hieroglyphics. The capitals of the columns are square, with a front face of Hathôr, to whom the temple was dedicated, on every side. These pictures fill a space of eight feet each; the plinth that crowns the capital is high; and the whole is completed by a rich entablature, surmounted with the bold cornice which is always so striking in Egyptian architecture. This beautiful structure, if clear of rubbish, would present a front of a hundred and sixty feet, with a height of sixty feet; the whole exhibiting a magnificent picture of nearly a thousand square feet, relieved by processions and other decorations.[3] Several chambers, attached to the interior of the temple, are covered with astronomical, or perhaps rather astrological decorations; and the calculations deduced from these occasioned at one time so powerful a prepossession in favour of their extreme antiquity, that some very obvious proofs of the contrary were overlooked. Comparatively speaking, the edifice is modern. As its basis rests on a terrace which is still nearly fifteen feet above the level of the neighbouring country, whilst similar terraces at Thebes are only on a level with the surface of the Nile, above which they were once greatly elevated, it may therefore be inferred generally, that the great temple at Denderah was not older than the time of the Ptolemies, or perhaps than that of the Romans. Such was the conclusion deduced by Visconti, and after him by Belzoni, whose practical investigations enabled him to ascertain the fact upon which the inference rests. But, on the other hand, Jollois, judging, as he says, from the style and execution of the sculptures, maintains that they cannot have been finished subsequently to the time of Cambyses.[4] Unfortunately for this opinion, however, the hieroglyphics upon the walls of the temple completely confirm the evidence afforded by the Greek inscription over the entrance of the pronaos, and establish the correctness of Visconti's conclusion. The epochs of the decoration may be very briefly stated. The most ancient part is the exterior wall at the extremities of the temple, where are figured in colossal proportions Cleopatra and her son Ptolemy Cæsar. The superior bas-reliefs belong to the time of Augustus, as also the exterior lateral walls of the naos, with the exception of some small portions, which only date from the reign of Nero. The pronaos is entirely covered with imperial legends of Tiberius, Caius, Claudius, and Nero; but in the interior of the naos, as well as in the chambers and edifices constructed upon the terrace of the temple, there does not exist a single sculptured oval or cartouch. None of the sculptures in these apartments go farther back than the time of Trajan or Antoninus; and they resemble that of the propylon on the south-east, which dates from the reign of the latter, and, being dedicated to Isis, conducted to the temple of that goddess, which is placed behind the great temple, dedicated, as already mentioned, to Hathôr or Venus. The grand propylon above described is covered with images of the emperor Domitian. With regard to the Typhonium, it appears to have been decorated under Trajan, Hadrian, and Antoninus Pius; but, from a Greek inscription, it would seem that one of the propylons was erected by the inhabitants of the nome in the thirty-first year of the reign of Augustus, A. D. 23.[5]

At, or rather a little below, Denderah, the Nile suddenly changes its course, and for about nine miles runs nearly due west, after which it resumes its original direction. Near the bend or elbow formed by the return of the river to its course, lay the town of Abydos, once the second city of the Thebaid; and at a small distance from the Nile, near the western mountains, was the residence of an ancient king, called Ismandis by the Egyptians, and Memnon by the Greeks. At the latter place are the remains of a fine building, which some antiquaries have agreed to denominate a Memnonium, but which is now known by the name of El-Berba or the temple. In one of the inmost chambers of the edifice Mr W. J. Bankes, in 1818, discovered a large hieroglyphical tablet, containing a long series of royal names, which have since been deciphered conformably to the principles first expounded and exemplified by Dr Young, and found in the main to correspond with those in the Royal Canon of Manetho. The interesting relic of antiquity thus discovered, and which has become so celebrated in hieroglyphical literature under the name of the tablet of Abydos, exhibits a genealogical table of the immediate predecessors of Rhamses the Great, the Sesostris of Herodotus, and, from the data which it furnishes, compared with other documents, enables us to ascertain, with some degree of probability, that Sesostris, under whom the sculptures were executed, must have ascended the throne of Egypt about the year before Christ 1473.[6] Further, the epoch thus determined, though certainly liable to some objections, is nevertheless supported by numerous concurring and independent testimonies, which, from their striking coincidence, warrant a reasonable expectation that the true era of Sesostris, which is the grand key to so many other important dates, will ultimately be fixed beyond the possibility of controversy.[1] The population of Abydos, as well as that of *Diospolis Parva* or Hô, appears to have been transferred to Ptolemais, the capital of the Thinite nome, at or near Syis, the Psoi or Soi of the Egyptians.[2]

---

[1] *Lettres écrites d'Egypte*, p. 90.

[2] " Non deplaise à personne," says Champollion, " les bas-reliefs â Dendérah sont *détestables*, et cela ne pouvait être autrement; ils sont d'un temps de décadence. La sculpture s'était déjà corrompue, tandis que l'architecture, moins sujette à varier puisqu'elle est un art chiffré, s'était soutenue digne des dieux d'Egypte et de l'admiration des tous les siècles." (*Lettres*, p. 91.) Mr Hamilton's opinion is diametrically opposed to that which is here expressed (see *Egyptiaca*, p. 193); and indeed it is not easy to conceive how architecture could sustain itself in a state of perfection " worthy of the gods of Egypt, and the admiration of all ages," if the other kindred arts had fallen into such a " detestable" condition as M. Champollion seems to intimate.

[3] Mr Hamilton speaks of this temple with unusual enthusiasm. " After seeing innumerable monuments of the same kind throughout the Thebaid," says he, " it seemed as if we were now arrived at the highest pitch of architectural excellence that ever was attained on the borders of the Nile. Here we found concentrated the united labours of ages and the last efforts of human art and industry, in that regular uniform line of construction which had been adopted in the earliest times." (*Egyptiaca*, p. 195.)

Girgé or Djirdjeh, the present capital of the Saïd, is situated half way between Abydos and Ptolemais, and about twelve miles south of the latter; and on a rising ground, distant nearly a mile from the river, lies Ikhmim, the ancient *Panopolis*, where the great dispenser of the generative, fructifying, and productive powers was devoutly worshipped.[3] The temples of Ikhmim, once so splendid, are now reduced to a few fragments. This place has about four thousand inhabitants, many of whom are Copts, and about one half Roman Catholics, principally engaged in the manufacture of coarse woollen cloths. Cau or Gau-el-kebir, or Great Gau,[4] the ancient *Antæopolis*, was at some distance from the river in the time of Ptolemy, but, owing to a change in the bed of the stream, which is constantly encroaching on the eastern side of the valley, it is now close to the Nile. Here was the pronaos or vestibule of a fine temple, which, by the encroachment of the river, had been severed from the eastern shore and insulated; but in 1819 it became a complete mass of ruins, in consequence of an unusually powerful inundation. The inscription on the pronaos proves that it was dedicated to Antæus, and the other gods worshipped in the same temple,[5] by Ptolemy Philometor, and Cleopatra his sister and queen, about 150 years before Christ; and it appears that the cornice was repaired by the Emperors Aurelius, Antoninus, and Verus, in the year 164 of our own era. The Siout of the Copts is the *Lycopolis* of the Greeks. The latter name was derived from the worship of the jackal, to which its inhabitants were peculiarly devoted. The only monuments of antiquity near Siout are some mounds of rubbish outside the town, and numerous sepulchres or catacombs in the neighbouring mountains. At Manfalout was an ancient city not mentioned by the Greek or Roman writers, and a little lower down the stream the catacombs are very extensive; whilst at Tarut-el-Sherif, still further north, the canal called Bahr Yussuf, or Joseph's River, branches off from the Nile, and passing along the base of the Libyan chain of hills, at length falls into the Birket-el-Keroun or Lake Mœris. The Shmoun of the Copts and the Ashmouneïn of the Arabs is the *Hermopolis Magna* of the Greeks. The ruins of Hermopolis cover an area of nearly four miles in circumference; but a portico, with a double colonnade, in a massive and uncommon style of architecture, forming one of the finest monuments of Egypt, and serving to convey some idea of the former splendour of this seat of the Egyptian muses, has recently been destroyed. The temple of Ashmouneïn was dedicated to Thoth, the Egyptian Hermes or god of wisdom, and the reputed inventor of the arts and sciences. The decline of Hermopolis may be dated from the building of Antinoë, now Sheikh Abadeh, on the opposite side of the river; a city founded by Hadrian in honour of his favourite Antinous. Its remains, consisting of colonnades, triumphal arches, baths, and ampitheatres, form a singular contrast to all the surrounding objects, and are quite foreign to the soil on which they stand. There are few columns standing; and those which are of granite have evidently been taken from more ancient edifices.[6]

Few remains of the cities which once flourished in the Heptanomis or northern part of Middle Egypt can now be discovered, yet quarries and catacombs continually mark out the spots on or near which they must have stood. At Beni-Hassan, on the eastern side of the Nile, are some remarkable excavations, many of which are adorned with paintings as fresh as when the colours were newly laid on; in the northernmost of these the ceilings are covered with planispheres similar to those at Thebes and Lycopolis, and the clustered columns which support the roof are formed in imitation of the trunks of palm trees. Most of the scenes and objects depicted in these *hypogæa* relate to domestic life, and some of the designs are said to be in the Etruscan style.[7] On the opposite side of the river, lower down, and close to the Bahr Yussuf, is Belmeseh, on

[1] The ruins at El-Kherbeh are supposed by Jomard to be those of the Memnonium. (See *Description de l'Egypte*, Antiq. tom. iv. pl. 35, p. 8.)

[2] De Sacy, *Abd-el-latif*, pp. 316, 571.

[3] The Egyptian name of Panopolis was Khemmo or Khemmis, whence the Coptic Khmim or Shmim. (Diodorus Sic. i. 18, p. 30; and Strabo, xvii. i. p. 457.)

[4] The Coptic name of this place, Tkoü, has been preserved in the Arabic. (Legh's *Travels*, p. 40.)

[5] This inscription has been skilfully restored by Letronne. (*Recherches*, pp. 42, 51.) At Cau or Gau, which is now a dirty Arab village, there are large quarries and numerous sepulchres. Here, too, the fabulous battle was fought in which Typhon and his adherents were defeated. (Diodor. Sicul. i. 21, p. 34.)

[6] Belzoni, *Researches*, &c. p. 29.

[7] Jomard, *Description de l'Egypte*; Hamilton's *Egyptiaca*, p. 297, et seqq.; Legh's *Travels*, p. 34. M. Champollion spent fifteen days at Beni-Hassan, during which time he was principally occupied in copying some of the designs in the catacombs. The subjects of these hypogæan delineations are, Agriculture; Arts and Trades; the Military Caste; Song, Music, and Dancing; the Training of Domestic Animals; Portraits; Games, Exercises, and Diversions; Domestic Justice; Family Circles; Historical and Religious Monuments; and, lastly, Zoology; the whole being calculated to throw much light on the manners, customs, habits, and pursuits of a singular people, who, both above ground and below it, sought to perpetuate the memorials of their civilization. The following descriptive details give us as it were an insight into the private life and habits of the ancient Egyptians.

"1. AGRIÇULTURE. Dessins représentant le labourage avec les bœufs ou à bras d'hommes; le semage, le foulage des terres par les béliers, et non par les *porcs*, comme le dit Hérodote; cinq sortes de charrue; le piochage, la moisson du blé; la moisson du lin; la mise en gerbe de ces deux espèces de plantes; la mise en meule, le battage, le mesurage, le dépôt en grenier; deux dessins de grands greniers sur des plans différents; le lin transporté par des ânes; une foule d'autres travaux agricoles, et entre autres la récolte du lotus; la culture de la vigne, la vendange, son transport, l'égrenage, le pressoir de deux espèces, l'un à force de bras et l'autre à mécanique, la mise en bouteilles ou jarres, et le transport à la cave; la fabrication du vin cuit, etc.; la culture du jardin, la cueillette des bamieh, des figues, etc.; la culture de l'ognon, l'arrosage, etc.; le tout, comme tous les tableaux suivants, avec légendes hiéroglyphiques explicatives; plus *l'intendant de la maison des champs* et ses secrétaires. 2. ARTS ET METIERS. Collection de tableaux, pour la plupart coloriés, afin de bien déterminer al nature des objets, et représentant le sculpteur en pierre, le sculpteur sur bois, le peintre de statues, le peintre d'objets d'architecture; meubles et menuiserie; le peintre peignant un tableau, avec son *chevalet*; des *scribes* et commis aux écritures de toute espèce; les ouvriers des carrières transportant des blocs de pierre; l'art du potier avec toutes les opérations; les *marcheurs* pétrissant la terre avec les pieds, d'autres avec les mains; la mise de l'argile en cône, le cône placé sur le tour; le potier faisant la panse, le goulot du vase, etc.; la première cuite au four, la seconde au séchoir, etc.; la coupe du bois; les fabricants de cannes, d'avirons et de rames; le charpentier, le menuisier; le fabricant de meubles; les scieurs de bois; les corroyeurs; le coloriage des cuirs ou maroquins; les cordonnier; la filature; le tissage des toiles à divers métiers; le verrier et toutes ses opérations; l'orfèvre, le bijoutier, le forgeron. 3. CASTE MILITAIRE. L'éducation de la caste militaire, et tous ses exercices gymnastiques, représentés en plus de 200 tableaux, où sont retracées toutes les poses et attitudes que peuvent prendre deux habiles lutteurs, attaquant, se défendant, reculant, avançant, debout, renversés, etc.; on verra par là si l'art Egyptien se contentait de figures de profil, les jambes unies

the site of the ancient *Oxyrynchus;* and still farther north, at the entrance of Fayoum, was *Heracleopolis Magna*, the Hnes of the Copts, and the Almas of the Arabs; but no trace of either city can now be discovered. The hatred of the crocodile, for which the inhabitants of Heracleopolis were noted, and their feuds with their neighbours the Arsinoites, have been recorded by ancient poets and historians. This city was sacred to the Egyptian Hercules, the founder and patron of irrigation by means of canals. Here the Nile passes close under the base of the Arabian hills, and leaves the most extensive as well as the richest tract of corn lands in all Middle Egypt.[1] The nome of Arsinoë is now called Fayoum, the Arabs having in this as in other instances preserved the Egyptian name. Its principal city was originally called *Crocodilopolis;* but this name was exchanged for that of *Arsinoë* by Ptolemy Philadelphus, who imposed the latter in honour of his sister. Medinet-el-Fayoum, or the city of Fayoum, is built from the materials, and is partly on the site, of the ancient capital Crocodilopolis; but the principal remains of the ancient city lie to the north of the present town, and occupy a space of two miles and a half by about two. Two ancient pedestals of colossal dimensions, and separated about a hundred yards, are called by the natives Pharaoh's feet; they are about thirty-three feet every way. A fallen obelisk of red granite, covered with hieroglyphical inscriptions, is also another monument of the ancient Arsinoë. To the north of Heracleopolis or Ahnas was *Aphroditopolis*, the capital of a nome bearing the same name, and situated between those of Heracleopolis and Memphis. Its Coptic name is Tpêh or Petpieh, whence the Arabs have formed Atfih, Atfieh, or Atafieh. Between Aphroditopolis and Memphis, but nearer to the latter, and at some distance from the western bank of the river, was the town of *Acanthus*, and a celebrated temple of Osiris situated in a grove of the Thebaic thorn, whence probably the town derived its name. But at none of these places are there any remains deserving particular description.[2]

According to the concurring testimony of ancient writers, the Labyrinth was a structure equal in magnitude to the Pyramids, and still more wonderful in its design. It was the work of several kings at that early period when there were almost as many sovereigns as nomes; and adjoining to it was the tombs of the princes by whom it had been erected. "I have seen that building," says Herodotus, referring to the Labyrinth, "and it exceeds all description. The same may indeed be said of the Pyramids, each of which, taken separately, is equal in value to many of the greatest works of the Greeks taken together; but the Labyrinth in truth excels even the Pyramids." It consisted of twelve courts, surrounded by covered porticoes, having their gates opposite to each other, six of them being turned to the north and six to the south, and the whole included within the same outer wall or enceinte; and there were two suites of chambers, the one under and the other above ground, and immediately over the former. These chambers were three thousand in number, namely, fifteen hundred above and as many below ground. The Greek historian went through and examined the chambers above, but he was refused admission to those below, which, it was alleged by the priests, were used as sepulchres for the sacred crocodiles, and for the kings who had erected the Labyrinth; a strange enough association, though not uninstructive with re-

---

et les bras collés contre les hanches. J'ai copié toute cette curieuse série de militaires nus, luttant ensemble; plus, une soixantaine de figures représentant des soldats de toute arme, de tout rang, la petite guerre, un siége, la *tortue* et le *bélier*, les punitions militaires, un champ de bataille, et les préparatifs d'un repas militaire; enfin, la fabrication des lances, javelots, arcs, flèches, massues, haches d'armes, etc. 4. CHANT, MUSIQUE, ET DANSE. Un tableau représentant un concert vocal et instrumental; un chanteur, qu'un musicien accompagne sur la harpe, est secondé par deux chœurs, l'un de quatre hommes, l'autre de cinq femmes, et celles-ci battent la mesure avec leurs mains: c'est un opéra tout entier; des joueurs de harpe de tout sexe, des joueurs de *flûte traversière*, de flageolet, d'une sorte de conque, etc.; des danseurs faisant diverses figures, avec les noms des pas qu'ils dansent; enfin, une collection très-curieuse de dessins représentant les danseuses (ou filles publiques de l'ancienne Egypte), dansant, chantant, jouant à la paume, faisant divers tours de force et d'adresse. 5. Un nombre considérable de dessins représentant L'EDUCATION DES BESTIAUX; les bouviers, les bœufs de toute espèce, les vaches, les veaux, le tirage du lait; la fabrication du fromage et du beurre; les chevriers, les gardeurs d'ânes, les bergers et leurs moutons; des scènes relatives à l'art vétérinaire; enfin, la basse-cour, comprenant l'éducation d'une foule d'espèce d'oies et de canards, et celle d'une espèces de cigogne qui était domestique dans l'ancienne Egypte. 6. Une première base du recueil ICONOGRAPHIQUE, comprenant les *portraits* des rois Egyptiens et de grands personnages. 7. Dessins relatifs aux JEUX, EXERCICES, et DIVERTISSEMENTS. On y remarque la *mourre*, le jeu de la *paille*, une sorte de *main-chaude*, le *mail*, le jeu de *piquets plantés en terre*, divers jeux de force; la chasse à la bête fauve, un tableau représentant une grande chasse dans le desert, et où sont figurées 15 à 20 espèces de quadrupèdes; tableaux représentant le retour de la chasse; le gibier est porté mort ou conduit vivant: plusieurs tableaux représentent la chasse des oiseaux au filet; un de ces tableaux est de grande dimension, et gouaché avec toutes les couleurs et le faire de l'original; enfin, le dessin en grand des divers piéges pour prendre les oiseaux; ces instruments de chasse sont peints isolément dans quelques hypogées; plusieurs tableaux relatifs à la pêche: 1, la pêche à la ligne; 2, à la ligne avec canne; 3, au trident ou au *bident;* 4, au filet; plus la préparation des poissons, etc. 8. JUSTICE DOMESTIQUE. J'ai réuni sous ce titre une quinzaine de dessins de bas-reliefs représentant des délits commis par des domestiques; l'arrestation du prévenu, son accusation, sa défense, son jugement par les intendants de la maison; sa condamnation et l'exécution, qui se borne à la bastonnade, dont procès-verbal est remis, avec le corps du procès, entre les mains du maitre par l'intendant de la maison. 9. LE MENAGE. J'ai réuni dans cette série, déja fort nombreuse, tout ce qui se rapporte à la vie privée ou intérieure. Ces dessins fort curieux représentent, 1, diverses maisons Egyptiennes, plus ou moins somptueuses; 2, les vases de diverses formes, utensiles et meubles, le tout colorié, parce que les couleurs indiquent invariablement la matière; 3, un superbe palanquin; 4, des espèces de chambre à portes battantes, portées sur un traîneau et qui ont servi de *voitures* aux anciens grands personnages de l'Egypte; 5, les singes, chats, et chiens, qui faisaient partie de la maison, ainsi que des *nains* et autres individus mal conformés, qui, 1500 ans et plus avant Jesus-Christ, servaient à désopiler le rate des seigneurs Egyptiens, aussi bien que, 1500 ans après, celle de nos vieux barons d'Europe; 6, les officiers d'une grande maison, intendants, scribes, etc.; 7, les domestiques portant les provisions de bouche de toute espèce; les servantes apportant aussi divers comestibles; 8, la manière de tuer les bœufs et de les dépécer pour le service de la maison; 9, une suite de dessins représentant des *cuisiniers* préparant des mets de diverses sortes; 10, enfin, les domestiques portant les mets préparés à la table du maitre. 10. MONUMENTS HISTORIQUES. Ce recueil contient toutes les inscriptions, bas-reliefs, et monuments de tout genre portant des legendes royales, avec une date exprimée, que j'ai vus jusqu'ici. 11. MONUMENTS RELIGIEUX. Toutes les images des différentes divinités, dessinées en grand et coloriées d'après les plus beaux bas-reliefs. 12. NAVIGATION. Recueil de dessins représentant la construction des bâtiments et barques de diverses espèces, et les jeux des mariniers, tout-à-fait analogues aux joûtes qui ont lieu sur la Seine dans les grands jours de fête. 13. Enfin, ZOOLOGIE. Une suite de *quadrupèdes*, d'*oiseaux*, de *reptiles*, d'*insectes*, et de *poissons*, dessinés et coloriés avec *toute fidélité* d'après les bas-reliefs peints ou les peintures les mieux conservées. Ce recueil, qui compte dejà près de 200 individus, est du plus haut interêt: les oiseaux sont magnifiques, les poissons peints dans la dernière perfection, et on aura par là une idée de ce qu'était un hypogée Egyptien un peu soigné. Nous avons dejà recueilli le dessin de plus de 14 espèces différentes de *chiens* de garde ou de chasse, depuis le *lévrier* jusqu'au *basset à jambes torses.*" (*Lettres écrites d'Egypte.*)

ference to the origin and real nature of animal worship.[1] The chambers above ground, which he had himself seen and examined, the same historian describes as greater than all other human works. The communications between these multitudinous chambers, and the winding passages leading from one court into another, were so varied as to occasion infinite surprise and no little dismay. These passages led from the chambers into porches, from the porches again into other apartments, and from these chambers into other courts; the roof and walls of all of them were of stone, and covered with sculptures; each court was surrounded by a colonnade of white stone, the blocks of which were joined as closely as possible; and at the angle which terminated the Labyrinth was a pyramid of forty orgyias, or about two hundred and fifty feet, in height, on which was sculptured large figures of beasts, and the entrance to which was under ground. Such is the account of this extraordinary structure given by Herodotus, from whom Strabo does not materially differ; but other ancient writers seem to be at variance with both, probably from not attending to the circumstance that the work was executed at intervals by different princes. Commenced by Mendes, it was continued by Tithoes or Petesuccus, and finished by the twelve kings, and Socharis the son of Sesostris. The pyramid of the Labyrinth alone remains.[2]

Still descending the Nile, and passing, for the present, Birket-el-Keroun or Lake Mœris, we come to the ruins of Memphis, the second capital of Egypt, the foundation of which was ascribed to the first king of that country, named Menes.[3] After the successive generations of Persians, Greeks, Romans, and Arabs, who have plundered Memphis in the wantonness of victory, or for the purpose of transferring its monuments to Alexandria or to Cairo, we may well wonder that, exclusively of those eternal structures the pyramids, enough should still remain to enable us to determine the exact site of this capital of the Pharaohs. The temple of Phtha, the Hephæstus or Vulcan of the Egyptians, was, according to Herodotus, a most wonderful edifice; and adjoining to it was a temple dedicated to Osiris, in which the sacred bull Apis was kept, another consecrated to Hathôr or Venus, and a third to Serapis. The Serapeion stood in a place where the sand was so loose and deep that the sphinxes forming the avenue in front of it were buried, some one half, and others up to the neck, and a person proceeding to the temple ran some risk if overtaken by a tempest, owing to the columns of sand raised and drifted about by the wind. Of the great temple of Memphis nothing but débris remains; yet the blocks of granite and breccia scattered about attest its dimensions to have been nearly equal to those of the most gigantic monuments of the Thebaid; whilst the fragments of columns, colossal statues, obelisks, and propyla, are perhaps the relics of the great northern vestibule, which is usually enumerated amongst the works of Mœris.[4] In the time of Strabo, Memphis was second only to Alexandria in point of size and population; and there were ports for shipping both before the city and the palace. The latter had been built on a rising ground near to the lower part of the town, in a grove of its own, with a port adjoining; but at the period when Strabo wrote it was unoccupied and in ruins. The site and name of this ancient city were well known in the twelfth and thirteenth centuries,[5] as appears from the account of it given by El-Idrisi under the denomination of Menph or Memph, which is merely an abbreviation of the Egyptian word *Memfi* or *Memphi.* Amongst the antiquities specified by Abdu'l-latif may be mentioned the Beit-al-akhdar or Green Tabernacle, a monolithic temple thirteen feet and a half in height, twelve feet in length, and ten feet and a half in breadth, having a chamber formed within it ten and a half feet in height, nine feet in length, and seven feet and a half in breadth, and covered both within and without with sculptures, some cut into the stone and some in relief, and with inscriptions in ancient characters. On the outside there was a representation of the sun in the eastern quarter of the heavens, with many figures of stars and spheres; in front were two large statues of stone, and within was one of gold representing Aziz, the eyes of which were two valuable gems. This tabernacle or temple was fixed upon a basis of large massive blocks of granite, and the monolith out of which it had been formed was of the same description of rock. Another monument also mentioned by the Arabian geographer was an idol or statue, consisting of a single block of red granite, which, exclusively of its pedestal, was about forty-six feet in height, fifteen feet from side to side, and from back to front in proportion. "What talent, resolution, and patience must have been combined to produce such works as these; what various instruments and unremitting labour; and to what an extent must not the forms and proportions of bodies, especially those of the human body, have been studied, to enable the artist to determine so exactly the mutual relations, distance, and proximity, as well as the corresponding articulations of every limb!" Such is the natural and just remark elicited from Abdu'l-latif after surveying the ruins of Memphis, which even in his time occupied a space of about nine miles in every direction. Yet so rapid has the work of destruction proceeded, especially since the fourteenth century, that few points have been more debated in modern times than the site of this celebrated city; and, excepting its pyramids, and the great plain of mummies, which attest the vicinity of the spot whereon stood the second capital of Egypt, it might almost be said, *Etiam periêre ruinæ.* But its distance from the Pyramids and the apex of the Delta having been clearly pointed out by Strabo, Pococke and Bruce were hence led to fix upon the neighbourhood of Mokhnan and Monyet-Rahineh, two villages on the left or western bank of the Nile, as the ground on which Memphis had once stood; and this opinion was completely established by the French during their occupation of Egypt. At Monyet-Rahineh, about one league from Sakhara, they found so many blocks of granite covered with hieroglyphics and sculptures around and within an esplanade three leagues in circumference, inclosed by heaps of rubbish, that they were convinced these must be the ruins of Memphis; and the site of some fragments of one of those colossuses which, according to Herodotus, were erected by Sesostris at the entrance of the temple of Phtha, would have been sufficient to expel their doubts had any remained.[1] The position, the distance from the fork of the Delta, the vicinity of the pyramids and the plain of mummies, and, in particular, the gigantic nature of the ruins themselves, all unite to prove that the site fixed on by Pococke and Bruce is the right one.

[4] Hamilton's *Egyptiaca*, p. 315. Belzoni was so much occupied in exploring the interior passages and chambers of the Pyramids, that he entirely neglected Memphis; and the same observation applies to a later and much more gifted traveller, M. Champollion. The latter indeed promised to examine the whole plain of Memphis, from Monyet-Rahineh to Djizeh; "je pousserai de là (Monyet-Rahineh) des reconnaissances sur Sakharah, Daschour, et toute la plaine de Memphis, jusqu' aux grandes pyramides de Gizeh; et après avoir couru le sol de la seconde capitale Egyptienne, je mettrai le cap sur Thèbes." But if he carried his design into execution, the results have not been communicated to us. (*Lettres*, p. 62.)

[5] *Geographia Nubiensis*, p. 98.

In those countries where absolute temporal power is allied with and reinforced by spiritual dominion, and where a superstition inflexible in its sway over the many readily lends all its influence to give effect to the will of one, believed to be the earthly representative or vicegerent of the gods, we may expect to find works executed, which in point of magnitude far surpass any thing to be met with amongst nations otherwise more favourably circumstanced in regard to liberty. When men live under the double thraldom of a despotism which wields the powers both of earth and heaven, and is identified with a system of religious belief, which recognises in the head of the state a lineal descendent of the gods, all their labour and all their energies must necessarily be at the command of a ruler who can thus give to his most arbitrary decrees the authority of religion, and whose own will is his only law; and hence it is in the power of a sovereign so circumstanced to accomplish undertakings which baffle ordinary calculations, and transcend all ordinary means. When Stesicrates proposed to Alexander to convert Mount Athos into a statue of the victorious monarch, the left arm of which should form the base of a city containing ten thousand inhabitants, while the right was to hold an urn whence a river should discharge itself into the sea, he assumed, on the part of the conqueror, an exercise of power over human agents, the most reckless and unsparing of which there is any example out of Egypt. In the latter country, the principle assumed by the Greek projector appears to have been systematically reduced to practice; the whole labour and energies of the nation were made available for the execution of the designs of its monarchs; and hence, in the unparalleled magnitude and durability of the public works which were reared under the Pharaohs, we have conclusive evidence of the complete and total subjugation of the people to their authority. Such a prodigality of labour and expense is compatible only with the supposition that it was lavished under the decrees of a merciless and inflexible despotism; and the hands of slaves were no doubt employed in elaborating the inextricable intricacies of the Labyrinth, or realising the vast conception of the Pyramids. Herodotus, it is well known, ascribes the largest of the Pyramids, that of Cheops, to a profligate and tyrannical prince, who compelled the people at large to perform the work of slaves, and, in the enormous structure which he reared, left an eternal monument of the merciless energy to which it owed its origin.

The number of pyramids scattered over Egypt is very great; but by far the most remarkable are those at Djizeh, Sakhara, and Daschour; and the first of these places, situated on the western bank of the Nile, and nearly in the latitude of Cairo, is distinguished above the others by possessing the three principal pyramids mentioned by Herodotus, and which are still justly numbered amongst the wonders of human art. The largest of these pyramids, which goes by the name of Cheops (Kobts or Kopts?), stands on an elevation upwards of a hundred and fifty feet above the subjacent plain; and although it has suffered much from human violence, immense heaps of broken stones having fallen down each side, and formed a high mound towards the middle of the base, yet the corners remain pretty clear; and, as the accumulation of sand is, owing to the elevation of the site, less than round the other pyramids, the foundation is easily discoverable, particularly at the north-west angle, though it is impossible to see along the line of the base, on account of the heaps of rubbish, or to make any accurate measurement thereof. The entrance is on the north side, nearly in the centre, or about an equal distance from each angle, and the passage slopes downward at an angle of about twenty-six degrees, for about a hundred feet from the entrance, when it opens into an apartment seventeen feet long, fourteen feet wide, and twelve feet high. From this apartment a similar passage ascends, at nearly the same angle, to another chamber of larger dimensions, being upwards of thirty-seven feet in length, seventeen feet in width, and about twenty feet in height, which is lined all round with large slabs of highly polished granite, whilst the ceiling consists of nine immense flags stretching from wall to wall. In this chamber, which does not reach beyond the centre of the pyramid, stands a sarcophagus of red granite, highly polished, but without sculptures or hieroglyphics; it is seven feet six inches in length, three feet three inches in width, and about as much in depth; but it has no lid, nor was any thing found in it except a few fragments of the stone with which the chamber is decorated. A third chamber, still higher in the body of the pyramid than either of the two just mentioned, was discovered by Mr Davison about sixty years ago; and the same apartment was recently entered and more fully explored by Mr Caviglia, who found its sides coated with red granite highly polished, and ascertained that the unevenness of the floor was occasioned by its having been formed of the individual blocks of syenite which constitute the roof of the chamber below. Mr Davison also discovered and descended into the well, as it is called, of which Pliny has left a description. It consisted of three distinct shafts, the first of which was twenty-two feet in depth, the second twenty-nine, and the third ninety-nine, thus making the total descent one hundred and fifty feet, or, including five feet between the first and second shaft, one hundred and fifty-five. But the latest and most complete survey of the secret chambers or caverns of the Pyramid of Cheops is that made by Mr Caviglia, who, besides sounding the depths of the celebrated well discovered by Mr Davison with nearly similar results, cleared out the principal passage into the pyramid, and having advanced as far as two hundred feet, discovered a door on the right hand, which opened into the bottom of the well; after which, finding that the passage did not terminate at the door-way, he continued his advance to the distance of twenty-three feet beyond it, when it took a horizontal direction for about twenty-eight farther, and ultimately opened in a spacious chamber, sixty-six feet long by twenty-seven broad, immediately under the central point of the pyramid. Communicating with this spacious apartment on the south side is a narrow passage, which runs horizontally into the rock for upwards of fifty feet, and then abruptly terminates; another at the end, which commences with an arch, and runs about forty feet into the solid rock of the Pyramid; and a third, which, however, is so obscurely mentioned, that neither its direction nor dimensions can be ascertained. It is much to be regretted that none of those who have occupied themselves in exploring these interior passages and chambers, should have thought of publishing a plan of them, which indeed is quite essential to enable us to understand their various ramifications and bearings. The greatest discrepancy has prevailed both in ancient and in modern times as to the height and magnitude of the pyramid of Cheops; so much so, that either the standards referred to must have been different, or the summit of the enormous structure has been considerably lowered since the days of Herodotus. The following table exhibits only a small portion of the variation which applies to the measurement and estimated bulk of this pyramid:—

---

[1] A plan of the ruins of Memphis, drawn by Jacotin, is given, along with a detailed account of them, in the *Description de l'Egypte.* The wrist of the colossus which M. Coutelle caused to be removed, and to which reference is made in the text, shows that, according to the ordinary proportions in such cases, it must have been about forty-eight feet in height.

As an approximation, therefore, we may assume with safety that the Great Pyramid is four hundred and eighty feet in height, on a base about seven hundred and fifty feet each way; or, in other words, that it covers an area of nearly eleven acres, and rises to an elevation of a hundred and twenty-seven feet above the cross of St Paul's, whilst its solid contents exceed seventy millions of cubic feet.[2]

The second pyramid, called that of Cephrenes, was entered and explored in 1816, by the indefatigable Belzoni, who has given an interesting account of his labour in accomplishing this object, in his *Researches and Operations in Egypt and Nubia*, to which we refer for the details. His first attempt was not attended with success; but being convinced that this pyramid was similar in construction to that of Cheops, he minutely examined the exterior of the Great Pyramid; and having corrected his calculations as to the point of entry, he searched more to the east on the northern face, and at length succeeded in discovering a granite entrance four feet in height and three feet and a half in width, which dipped towards the centre for more than a hundred feet, at an angle of twenty-six degrees. Having removed the rubbish by which this passage was obstructed, he found his progress stopped by a block of granite, which proved to be a portcullis, and seemed to present an insuperable barrier to the prosecution of his researches. "It stared me in the face," he observes, "and said *ne plus ultra*, putting an end, as I thought, to all my projects." But on close inspection, he discovered that a regular groove or cavity had been formed to receive this portcullis; and as it happened to be elevated about eight inches from the lower part of the groove, thus leaving a considerable aperture underneath, he was enabled gradually to raise it. Here, however, the granite passage ceased, and a horizontal passage of nearly the same dimensions opened and extended about twenty-three feet, terminating at a shaft or well fifteen feet deep. Having descended the latter by means of a rope, the adventurous explorer found another passage with the same angle of inclination as that by which he had first descended, but running in a contrary direction, and off from the centre; and from the bottom of the well a passage also ran towards the centre of the pyramid. Following the latter, which proceeded in the direction just mentioned, Belzoni soon found that it terminated in a chamber at the centre of the pyramid. On entering this chamber, which he afterwards found to be forty-six feet in length, upwards of sixteen feet in width, and between twenty-three and twenty-four feet in height, he searched for the sarcophagus, which, after some delay, he found sunk into the floor. It was of the finest granite, about eight feet in length, three feet and a half in width, and above two feet in depth, and was surrounded by large blocks of granite, placed so as to prevent its removal; but the lid having been drawn to one side, was broken, and not a single sculpture or hieroglyph was to be found upon it. Some bones, said to be those of a bull, were discovered mixed with the rubbish. This chamber, which is nearly of the same dimensions as that of the Great Pyramid, and which is cut out of the solid rock, appears, from an Arabic inscription written in charcoal, and transcribed by a Copt employed by Belzoni for the purpose, to have been visited by the curious of a former age. The indefatigable explorer then returned to the well or shaft, and proceeding along the passage of the centre already mentioned, found that at the distance of forty-eight feet it communicated with a horizontal passage, also running outwards to the length of fifty-seven feet. A side passage led into a chamber, which however contained nothing save an inscription like that found in the first. From the extremity of the horizontal passage another was found to run inwards with a rise of twenty-six feet, until it terminated at the base of the pyramid, which thus appears to have had two entrances. In this last passage, as in the other, there is a groove for a portcullis.[3] The dimensions of the pyramid thus opened and explored were ascertained by Belzoni to be as follow :—

[1] Russell's *View of Ancient and Modern Egypt*, p. 149.

[2] Vide Nouet's Report to the Institute at Cairo, published in the account of their proceedings; also Hamilton's *Egyptiaca*, p. 325. Captain Head's estimate, however, is considerably greater than that which is given in the text. "This pile, as it now stands," says he, "is in altitude nearly 150 feet above the cross of St Paul's, and is ascended on each side by steps, having their lower layer resting on a space equal in size to Lincoln's Inn Fields, one side being 780 feet....The solid contents of the Pyramid of Cheops exceed 75,000,000 cubic feet....Viewing these masses, the soul shrinks abashed and awe-stricken, and reflects upon the countless generations which have been swept from the earth, and how many more they are destined to survive." (*Eastern and Egyptian Scenery, Ruins*, &c. p. 46.)

[3] *Researches and Operations in Egypt and Nubia*, p. 267, et seqq. The opening of this pyramid had so long been considered an object of so hopeless a nature that, as Mr Salt has observed, it is difficult to conceive how any person could have been found sanguine enough to make the attempt; and even after the laborious discovery of an entrance which had to be forced, it required great resolution and

The base, each side	684 feet.
The perpendicular height	456
The coating, from top to where it terminates	140

These pyramids are said to have been coated or cased from top to bottom; and indeed forty feet of coating still remain on that of Cephrenes. But the Great Pyramid has no appearance of having been touched in this way; and on that of Cephrenes the coating was probably never completed, as no indications of it were discovered by Belzoni when removing the sand from its base. The next pyramid, called by the name of Mycerinus, and situated beyond that of Cephrenes, seems to have been cased with granite; at least fragments of that material were found amongst the rubbish. This pyramid still remains to be opened by some future traveller, Belzoni having failed in the attempt. It is only about a hundred and sixty feet in height; and beyond it is another of still smaller dimensions, having its summit crowned by one large block of stone, as if for a pedestal. The stability of these enormous piles is increased by the stones having been fixed so as to slope inwards; and so perfectly have they been adjusted, that not one of them has swerved from its position. As nothing but the solid rock itself could have formed a foundation for such structures, a sufficient space was levelled, part of the hill being escarped for the purpose. The pyramids of Sakhara are three miles south of those of Djizeh, and the pyramids of Daschour are beyond those of Sakhara, whilst many more of brick or of stone are scattered over the plain, intermixed with the excavations, cemeteries, and fragments of statues or edifices, extending over a space of several miles, and serving to mark out the site of the second capital of the Pharaohs. Fronting the river, and opposite the pyramid of Cephrenes, the colossal Sphinx reclines in ample majesty, a proper companion for the mighty piles which we have been considering. It is hewn out of the solid rock, and is covered with hieroglyphics and symbols of various kinds. Through the persevering exertions of Mr Caviglia, the whole statue was laid open to its base, and an area cleared to the extent of a hundred feet from its front. On the digits of the left paw are several indistinct legends and an inscription in verse, which Dr Young has restored; on those of the right are a few of the usual dedicatory phrases, which it is unnecessary to repeat here.

As the pyramids have neither inscriptions nor bas-reliefs or sculptures of any kind, we are left entirely to conjecture as to the period at which they were erected, or the uses to which they were appropriated. One circumstance, however, is most remarkable. In all the pyramids which have been opened, whether at Djizeh or Sakhara, amounting to at least six, the entrance has in every case been discovered near the centre of the base of the northern face; and the passage inwards from the exterior entrance has as uniformly been found to slope downwards at an angle which never varies. In the Great Pyramid, the inclination of the passage is stated by Greaves at twenty-six degrees; but Caviglia determined it at twenty-seven; and this angle is common to all the sloping passages in the edifice. The same conclusion was formed by Belzoni in regard to the pyramid opened by him, the angle in all the sloping passages or channels being about twenty-six degrees; and on opening one of the small pyramids towards the south, Caviglia found the inclination of the passage the same, whilst at the end of it were two chambers connected together, and both empty. Now, as it is scarcely possible that this coincidence could have been accidental, it has been concluded that these passages or tubes were connected with the celebration of some great festival, the time of which was determined by observing the transit of some particular star across the meridian below the pole, whence an accurate measure of sidereal time, an object in itself of great importance, might also be obtained. But, whilst it would not be easy to devise a method better adapted for observing the transit of a star with the naked eye, than watching its motion across the exterior orifice of such a lengthened tube, yet no safe conclusion can be deduced from the coincidence of inclination alluded to; first, because there is reason to suspect that we have not yet got the true measure of the angle which these passages form with the plane of the horizon; secondly, because it has not been ascertained whether the angle of inclination is the same in all the pyramids which have been opened, or whether there is a difference in the angles of the approaches of the pyramids of Djizeh, Sakhara, and Daschour, corresponding to the difference of latitude of these several places; and thirdly, because, from an expression made use of by Mr Caviglia, it would seem that in one at least of the pyramids opened, the angle of inclination was equal or nearly so to the elevation of the pole, or the latitude of the place. In short, the material facts on which alone any reasoning can be built have not yet been ascertained with sufficient accuracy and precision to warrant the inference which has been somewhat hastily drawn from them, although, as a mere conjecture or hypothesis, it has a reasonable degree of probability in its favour, especially if we consider the exact position of these structures with reference to the four cardinal points. At the same time, there is every reason to believe that these enormous piles were used for other than astronomical purposes. The bones found in the chamber of the pyramid of Cephrenes, not to mention other circumstances, seem to indicate some connection with the worship of Apis; and besides, from the care with which the entrances appear to have been concealed, it is not impos-

---

confidence in his own views to induce the discoverer to continue the operation, when his predecessors, possessed of much greater means, had completely failed. It is not much to be wondered, therefore, that Belzoni should have felt disposed to resent conduct such as that which is described in the following extract:—" One thing more I must observe respecting the Count de Forbin. On his return from Thebes, I met him at Cairo, in the house of the Austrian consul. I had begun the task of opening the Pyramids, and had already discovered the false passage. The count requested, in a sort of sarcastic manner, when I had succeeded in opening the Pyramid, which no doubt he supposed I never would, that I would send him the plan of it, as he was about setting off for Alexandria the next day, and thence to France. I thought the best retaliation I could make was to send him the desired plan; and I did so as soon as I opened the Pyramid, which was in a few days after his departure. Would any one believe that the noble count, on his arrival in France, gave out that he had succeeded in penetrating the second pyramid of Djizeh, and brought the plan of it to Paris? Whether this be the fact or not, will appear from the following paragraph taken from a French paper now in my possession: —' On the 24th of April, Monsieur le Comte de Forbin, director-general of the Royal Museum of France, landed at the lazaretto of Marseilles. He came last from Alexandria, and his passage was very stormy. He has visited Greece, Syria, and Upper Egypt. By a happy chance, some days before his departure from Cairo, he succeeded in penetrating into the second pyramid of Djizeh. Monsieur Forbin brings the plan of this important discovery, as well as much information on the labours of M. Drovetti at Karnak, and on those which Mr Salt, the English consul, pursued with the greatest success in the valley of Beban-el-Malook, and in the plain of Medinet-Abou. The museum of Paris is going to be enriched with some of the spoils of Thebes, which Monsieur Forbin has collected in his travels.' Was this written," exclaims Belzoni, " by some person in France, in ridicule of the Count de Forbin, or is it an attempt to impose on the public by a tissue of falsehoods?" (Vol. i. p. 393.)

sible that, both in the pyramid of Cheops and in that of Cephrenes, there may yet be many undiscovered chambers. The chamber which contains the sarcophagus in the former is equal to a good-sized drawing-room; but there might be five thousand such chambers within the pyramid; and as structures so enormous must have been reared for some great object, or what was considered as such, it is probable that much still remains to be discovered in their interior. It is not impossible that the records of the kingdom of the Pharaohs may yet peradventure be found in some crypt "far ben" in these eternal register-houses.[1]

In speaking of the mechanical labours of the ancient Egyptians, it is impossible to pass unnoticed Lake Mœris, which is described by Herodotus as not less wonderful than the Labyrinth. Its circumference, he informs us, measured three thousand six hundred stadia, making sixty schœni or four hundred and fifty miles; an extent equal to the sea-coast of Egypt. Its greatest length stretched from north to south, and its greatest depth was not less than fifty orgyias, or thirty-six fathoms. He is of opinion that it was excavated by the hand of man; and his reason for this belief is, that about the middle of the lake there were two pyramids, each fifty orgyias, or two hundred and twelve feet above, and as much below the water, whilst on the summit of each there was placed a colossus of stone, in a sitting posture, or throned. The waters of this lake, he adds, were entirely derived from the Nile, and its fisheries paid one talent of silver, or L.225, to the crown, every day for six months during the decrease of the waters, and twenty minas, or L.75, for the remaining six months during their increase; thus yielding an annual revenue of L.54,000. Herodotus also states, on the authority of the inhabitants, that this lake has a subterraneous channel, or passage, westward into the Libyan desert, in the line of the mountain which rises above Memphis; and, from those who dwelt on its shores, he further learned that the earth dug out of the excavation which formed the lake was thrown into the river, and washed down by the current into the sea; an explanation with which he appears to have been perfectly satisfied. This account, exhibiting the characteristics of simplicity and truth, is substantially confirmed by the statements of Diodorus Siculus and Pomponius Mela, except that the latter makes the circumference five hundred miles instead of four hundred and fifty; and all coincide in the opinion that its object must have been to save the country from the effects of an excessive inundation, by affording a receptacle for the surplus flood, and at the same time to keep in reserve a supply of water for the parched lands in the vicinity, or to meet the wants of a dry season in the Delta. But, as the water of this lake has a disagreeable taste, and besides is almost as salt as the sea, contracting its saline property from the nitre with which the surrounding land is everywhere impregnated, it is probable enough that it was originally constructed rather to prevent an evil than to secure a benefit, to counteract an excessive rather than to eke out a deficient inundation.

The dimensions of this lake in modern times do not in any degree correspond with the statements which have been recorded by the ancients. According to Pococke, at the time when he visited Egypt it was only about fifty miles in length and ten in breadth; and Mr Browne, who travelled at a still later period, estimated the length at between thirty and forty miles, and the breadth at not more than six miles. It appears, therefore, that the limits of this inland sea have been much contracted; and further, that the process of diminution is going on at a rate distinctly perceptible. Anciently the waters of Lake Mœris covered a large portion of the valley of Fayoum, and, when the inundation exceeded a certain height, probably found an outlet from the north-eastern extremity, along the course of the Bahr-bilama or Waterless River, thus reaching the sea to the westward of Lake Mareotis and Alexandria. That the Nile originally flowed through the valley of the Natron Lakes, is now generally admitted; and the opinion is strengthened by the conformation of the adjoining country, the existence of the bed or channel of a river, extending to the sea, but now dry, and more especially by the escarpment of the chain of mountains, shutting the entrance of the valley north of the Pyramids, which appears to have been caused at some period by the action of the running water, as may indeed be observed in all the mountains at the base of which the Nile flows at the present day. In its present contracted dimensions, Lake Mœris is called by the Arabs Birket-el-Keroun, the Horn or Bow Lake, being so named either from its figure, or from the celebrated ruin near to its south-western extremity, denominated Kasr Keroun by the Arabs, and till lately supposed to form part of the Labyrinth. The canal called Bahr Yussuf, or Joseph's River, is about a hundred and twenty miles in length, and, on entering the province of Fayoum, is divided into a number of subordinate branches, supplied with a variety of locks and dams. Two other canals also communicated between the lake and the stream, and, by means of the sluices at their junction with the river, admitted or excluded the water, according as the Nile rose above or fell below a certain limit. These were the principal achievements of Mœris, whose works are to be sought for not so much in the lake which bears his name, and seems to be rather a natural basin skilfully appropriated to a purpose of great public utility than a work of labour and art, as in the immense cuts and excavations which connected this lake with the Nile, and in the mounds, dams, and sluices, which rendered it available for extensive and systematic irrigation, the prime cause of fertility in Egypt. We shall not attempt here to describe the reticulation of canals, and other works therewith connected, by means of which this beneficent object was in a great measure insured, and a sort of equilibrium established in the supply of the fluid so essential for the purposes of cultivation; but shall merely content ourselves with observing, that the author of such works of unquestionable utility is the real benefactor of his kind, and that the glory which encircles the name of Mœris-Thouthmosis is a thousand times more enviable, because more beneficent in its character, than that of the founder of the Labyrinth, or of the merciless taskmaster who reared the Great Pyramid.

In this land of wonders there are many other works and monuments well deserving of being described; but the limits assigned to the present section having been already exceeded, it is necessary to bring it to a close, without entering into details which would be found to possess only a secondary kind of interest. We cannot conclude, however, without expressing our deep regret that, under the comparatively enlightened government which has now been established in Egypt, the destruction of ancient monuments should be carried on with a systematic and calculating perseverance, which, unless checked, must in a few years annihilate the finest and noblest remains that have escaped the united ravages of time and barbarism. Let us hope, however, that the viceroy may be induced to interpose, and that present convenience or advantage will no longer be purchased at so heavy a cost to art and antiquity.[1]

SECTION VI.

PANTHEON OF EGYPT.

Knuphis or Agathodæmon.—Phtha or Phthah.—Neïth.—Ré or Phré.—Rhea.—Ioh.—Apopis.—Kronos.—Thoth.—Osiris.—Aruëris.—Typhon.—Isis.—Nephthé.—Thueris.—Bebon.—Ares.—Shom or Somus.—Buto.—Horus, Hor, or Horsiêsi.—Harpocrates.—Anubis.—Arsaphes.—Athôr or Hathôr.—Amun or Amoun.—Mendes.—Busiris.—Macedon.—Bubastis.—Sarapis.—Shmun or Esmunus.—Paamyles.—Tithrambo.—Thermuthis.—Canopus.—Menuthis.—Besa.—Proteus.—Nilus.—Apis.—Mneuis or Mnyis.

In the selection of authorities respecting the principal deities worshipped by the Egyptians, it will be most convenient to consider the respective personages in their chronological, or rather genealogical order, as far as any evidence can be obtained to ascertain their places in the mythological system.

AGATHODÆMON, *Cneph*, *Chnuphis*, or *Knuphis*, appears to be the oldest representative of the divine power admitted by the Egyptians, although his attributes are not distinctly ascertained, except as the parent of Phtha, whose origin is referred, in the works of the spurious Hermes, to an egg of *Cneph* or *Kneph*, which is perhaps the Coptic IHHNIFI, or *genius of spirit*. Even before this Cneph we are told of the existence of an *Eicton* or *Icton*, which has been supposed to mean IHHTHO, or *genius of the whole world;* but this seems to have been a sort of chaos, and the personification is not generally admitted. Eusebius makes Cneph distinctly synonymous with Agathodæmon; and this interpretation seems to identify the term with the *Knuphis*, of whom Strabo mentions a temple in Elephantiné, since IHHNUFI would naturally mean *good genius*, the word NUFI occurring frequently in other compounds. In a Greek inscription now in the British Museum, the emperor Nero is called the good genius of the world, and the winged globe hovering over the inscription seems to allude to this piece of flattery; but the Knuphis or Knumis of the amulets of later times is a serpent or a dragon raising itself on its tail, having rays about its head, and surrounded with stars. The name of Agathodæmon is inserted by Manetho amongst the fabulous kings, immediately before Kronos.

---

[1] It would perhaps be too much to expect that Mehemmed Ali, engrossed with objects of present ambition, should evince any very decided predilection for "Egypt's elder time," or give himself much trouble to conserve the monumental remains of twenty-five dynasties of kings. The viceroy, we fear, is too decided an utilitarian to concern himself about objects of antiquarian research or learned curiosity; and it is highly probable that a kaleidoscope, a magic disc, or any other ingenious scientific toy, would interest him much more deeply than the discovery of a new cella in an old temple, or a translation of a hieroglyphic inscription, enumerating the titles and narrating the campaigns of Sesostris. At the same time it would be exceedingly desirable if he could be made aware that, however little he may care about such matters, they are of importance to others; and that the wanton demolition of monuments which has of late years taken place under the eyes, and even by the directions, of some of his agents, is calculated to deprive the country over which he rules of its principal attraction to European visitants. Nothing, we should think, would be more easy than to make the pasha comprehend that he has a direct and tangible interest in at least preventing the continuance of the barbarity which has recently been in so many instances committed; and if the European residents in Egypt were to join in a representation on the subject, there can scarcely be a doubt that it would have the desired effect. In the year 1829, M. Champollion, whilst on the eve of quitting Egypt, transmitted to the viceroy a *Note* "pour la conservation des Monumens de l'Egypte," in which the conduct of his agents was very pointedly denounced, the extent of the havoc committed by them clearly detailed, and the precautions necessary to be adopted in order to arrest the progress of the evil distinctly specified; but this representation being unsupported, and many of the collectors of antiquities at Alexandria and Cairo secretly encouraging the dilapidations complained of, in the despicable view of giving a factitious value to their collections, it produced no sensible effect, and the work of destruction has since gone on with but little interruption. Accordingly, some of the finest monuments of ancient Egyptian civilization, which had outlasted the casualties of forty centuries, and the ravages of five conquests, have lately perished by the hands of destroyers more barbarous and unsparing than either the wild Persians of Cambyses or the fanatical Arabs of Amru.

Among the Europeans who visit Egypt there is annually a great number who, not being attracted thither by any commercial pursuit, are only actuated by a desire to contemplate on the spot the remains of ancient splendour and renown, and to examine for themselves the vestiges of the first form of civilization of which any trace has descended to modern times; and as these persons may now, under the protection of the viceroy's vigorous government, pursue their inquiries in perfect safety, it is obvious that their sojourn in the different provinces of Egypt and Nubia must entirely depend on the monuments which are scattered along both banks of the Nile, and that whilst science and literature may be enriched by their observations, the country itself must also be benefited by their personal expenditure, whether disbursed in the employment of labour to clear out monuments, in satisfying an active curiosity, or in the acquisition of divers products of ancient art. In short, as a large amount of capital is annually imported into Egypt by travellers of this description, it is clear that the government of the viceroy, if it consulted the real interest of the country, would devote its attention to the conservation of those edifices and monuments which form the principal, if not the sole objects for which such travels are undertaken by a crowd of individuals belonging to the most distinguished classes of European society; that, so far from permitting wanton and gratuitous destruction, it would adopt measures to arrest even the progress of ordinary decay; and that its subordinate functionaries, instead of being the destroyers, would be made the protectors and defenders of the Cyclopian works of ancient days. The actual case, however, is far different from this; and learned Europe now bitterly deplores the entire destruction of a crowd of ancient monuments, the demolition of which has been so complete that not the least trace of them remains.

But, to come to particulars, amongst those which have been recently destroyed are, *first*, all the monuments of Scheik-Abadeh, of which there now only exist some granite columns, that, from their dimensions and hardness, appear to have defied the efforts of the destroyers; *secondly*, the temple of Aschmuneïn, one of the finest monuments of Egypt; *thirdly*, the temple of Kau-el-Kebir, which the Nile had partially undermined, thereby facilitating the work of demolition; *fourthly*, a temple to the north of the town of Esneh; *fifthly*, a temple opposite Esneh, on the right bank of the river; *sixthly*, three temples at El-Kab or El-Eitz; and, *seventhly*, two temples in the island opposite Assouan, the ancient Syené, called Geziret-Assouan. From this enumeration, then, embracing only a short period, and excluding the destruction of the last two years, it appears that thirteen or fourteen ancient monuments, three of which in particular were of the very highest interest to travellers and learned men, have been entirely demolished. But the positive loss, great as it is, falls far short of that with which the learned world is threatened from the progress of this systematic dilapidation, which, if it continues to advance in a similar ratio, will in ten years hence level with the ground the principal edifices and monuments of Egypt and Nubia. We are not without hopes, however, that the viceroy may be induced to interpose his authority in order to arrest these deplorable devastations. M. Champollion laid before him a *catalogue raisonné* of the monuments both of Egypt and Nubia, at the same time indicating the means proper to be adopted for their future preservation; and other individuals of weight will, we trust, exert their influence with Mehemmed Ali in order to persuade him to take the necessary steps for accomplishing the object desired. If his highness would only take upon himself the character of conservator of

Those temples, palaces, and piles stupendous,
Of which the very ruins are tremendous,

he would entitle himself to the gratitude of all Europe, at the same time that he advanced his own real interest and glory; for, besides the advantages to which we have already alluded, it ought to be kept in view that the temples, palaces, tombs, and all other kinds of monuments, which still attest the power and greatness of the Pharaohs and the Ptolemies, are at the same time the noblest ornaments of modern Egypt.

The same authority attributes a still higher antiquity to PHTHA, whom it places as the first of the fabulous kings of Egypt; he is universally considered as the great ancestor of the other deities, and is especially called the father of the sun, as we learn from various chronologers, as well as from Callisthenes and others. He seems to have been a personification of the creative, and perhaps of the generative power, designated under the character of a workman or an architect. He is sometimes compared to Prometheus, as the discoverer of fire; but Hephæstus or Vulcan is his common representative in the Greek and Roman mythology; although it must always be remembered, that, *between the imaginary personages of different nations the identity must naturally be accidental and imperfect.* Cicero and Eusebius mention Phtha as the same with Vulcan; and Eratosthenes, on the authority of the Egyptian priests, interprets MOEPHTHA, *Philephæstus* or *loving Vulcan*, which in Coptic would be exactly expressed by MAIPHTHAH, as MAISON is *loving a brother.* Mr Akerblad quotes from a Coptic sermon of Sinnethi the words, "Hephæstus, who is Phtah;" and this remarkable passage proves, as he justly observes, how much Jablonsky was mistaken in his orthography of *Phthash*, on which he founded one of his fanciful etymologies.

NEITH, the Minerva of the Egyptians, had a celebrated temple at Saïs, in which was the well-known inscription respecting the goddess of universal nature, whose offspring, in the translation of the inscription, as preserved by Proclus, is said to be the sun. It seems therefore natural to call Neïth the wife of Phtha; as Plato also observes that arts were invented by Vulcan and his wife; but we are told that Neïth is to be considered as both male and female. The name is mentioned by Plato as synonymous with Minerva, and Eratosthenes explains Nitocris, Minerva the victorious.

RE, or PHRE, *the Sun*, otherwise called ON, is mentioned by Manetho as the son of Vulcan. He married Rhea, and having discovered her infidelity, condemned her to bear no offspring on any day or any night of the whole three hundred and sixty that then composed the year. Plutarch says that he was represented by a young child rising out of a lotus; but this emblem is more attributable to Horus, who is another of the forms of the solar power, and is sometimes improperly confounded with Apollo. The word *Phré* is often found in Greek letters on the amulets, accompanied by emblems of the sun.

RHEA, the wife of the Sun, may perhaps have derived her name from *Ré;* she appears to be identical with the *Urania*, or female Heaven, of Horus Apollo, the Coptic PHE being feminine. Jablonsky makes Rhea the same with Athôr or Hathôr, but he adduces no sufficient authority for the opinion. She is said to have been familiar both with Kronos and with Thoth; and Diodorus calls her the wife and sister of Kronos.

IOH, *the Moon.* Plutarch tells us that Hermes played at dice with the Moon, probably as presiding over the calendar, in order to gain a time for the birth of Rhea's children, and to evade her husband's curse; so that the Moon must be considered as one of the oldest deities. The Egyptian name being masculine, the Moon can scarcely have been worshipped as a goddess; and whatever relation may have been imagined to exist between Isis and the lunar influence, the two deities were certainly not identical.

APOPIS, a brother of the Sun, is mentioned by Plutarch as having made war against Jove. But the Jupiter of Manetho stands much lower on the list, the order being Vulcan, the Sun, Agathodæmon, Kronos, Osiris with Isis, Typhon, Horus, Ares, Anubis, Hercules, Apollo, Ammon, Tithoes, Sosus, and Jupiter; the last nine being denominated semigods.

KRONOS, or *Saturn*, is only known from his connection with Rhea, the wife of the Sun. His character probably bore some relation to a personification of Time and Antiquity.

THOTH, *Theuth*, or *Taaut*, one of the most celebrated of the Egyptian deities, is sufficiently identified with Hermes or Mercury, by the testimony of a variety of authors. Diodorus mentions him as the scribe or secretary, and privy counsellor of Osiris. He is generally considered as the inventor of letters and of the fine arts. Plutarch and Horus Apollo observe that he was typified by the ibis, which was sacred to him. Plutarch also says that he had one arm shorter than the other.

OSIRIS, properly OSHIRI or OUSIREI, meaning in Coptic *energetic* or *active*, which is precisely one of Plutarch's interpretations of the name, was the deity most universally adored throughout Egypt, and possessing the principal attributes of Bacchus, Adonis, and Pluto; besides being often compared to the Nile, and sometimes to the Sun. He was genealogically considered as the son of the Sun and of Rhea; and at his birth, on the first of the supplementary days of the calendar, a voice was heard, proclaiming that he was Lord of all. He married his sister Isis, and, according to Diodorus, left her to govern his kingdom during his military expeditions, resembling those of Bacchus, being accompanied by Pan, Hercules, and Macedon, having a ship which was the prototype of the Argo of the Greeks, with Canopus for his pilot. He was at last treacherously shut up alive in a coffin by Typhon, aided by seventy-two conspirators, together with an Ethiopian queen Aso. The coffin, being thrown into the Nile, was carried to one of its mouths, and there left on shore: it became afterwards inclosed in the trunk of an erica, which grew round it, and which constituted one of the columns of King Malcander's palace; but the body escaped from its confinement, and was found by Typhon as he was hunting; he divided it into fourteen parts, which were afterwards found scattered in different places by Isis, and buried separately. Osiris, however, returned from the dead to console his wife, and to conduct the education of his son Horus. There was a mystery in his identification with Pluto, of which the old authors affect to speak with reverence. His dress was generally white, but sometimes black. He is represented as carrying a whip, which is supposed to be intended for the punishment of Typhon. Plutarch says that he is typified by a hawk, and denoted hieroglyphically by an eye and a sceptre.

ARUERIS, a twin-brother of Osiris, and, like him, the son of the Sun and of Rhea, was born on the second supplementary day. He is also called the elder Horus, and is considered by some of the Greeks as their Apollo.

TYPHON, the spurious son of Rhea and Kronos, was born on the third supplementary day, and married his sister Nephthé. He is characterized by a red colour, and is supposed to have been a personification of the effects of scorching heat. He is also compared to the earth's shadow, as causing eclipses of the moon. The celestial habitation of his soul was supposed to be in the Great Bear. According to Plutarch, his Egyptian names were *Seth, Bebon*, or *Babyn*, and *Smy;* the word Typhon being apparently of Greek origin.

ISIS, ISI, or ESI, was supposed to be the offspring of

Thoth and Rhea, born on the fourth supplementary day; she was also sometimes called the daughter of Prometheus. She is generally compared to Ceres, or the Earth, and is made the deity of fertility and of maternal love. She was also esteemed analogous to Proserpine, as the queen of the lower regions, and the wife of Pluto; thus she is called by Aristides "the saviour and conductress of souls;" and, in some Roman inscriptions copied by Zoëga, she is made "the guardian of the ashes of the dead." Horus Apollo says that her head was sometimes adorned with vultures' plumes; but Herodotus tells us that she was represented with cow's horns, like Io; other authors however say that, after Horus, in revenge for his father's death, had made Typhon prisoner, Isis imprudently set him at liberty, and Horus, therefore, tore the regal diadem from her brow, but that Thoth or Hermes substituted for it a helmet made of a bullock's head. Her soul was supposed to have its residence in the Dog Star, the Sothis of the Egyptians. Her dress was of many colours. She is sometimes compared to the moon; but this idea appears to be foreign to the oldest mythology, as well as to the genius of the Egyptian language. She has also been somewhat arbitrarily confounded with Minerva by Plutarch, in speaking of the inscription of the temple of Sais, which confessedly related to the Egyptian Minerva, who was indisputably the goddess Neïth; although in consequence of this inattention, the "robe" mentioned in the inscription has been called the "robe of Isis," and the expression has been almost proverbially employed as denoting mystery and secrecy.

Nephthe, rather than *Nephthys*, the spurious daughter of Rhea and Kronos, was born on the fifth supplementary day. She is sometimes called by the Greeks *Teleuté*, that is, consummation; and sometimes Venus and Victory. She is mentioned by Firmicus as the sister and companion of Isis; and Plutarch says that the face of Isis was sometimes represented on the sistrum, and sometimes that of Nephthé.

Thueris, a concubine of Typhon, is only noticed as having been pursued, on her way to visit Horus, by a huge snake, which was killed by Horus' people.

Bebon, who is sometimes confounded with Typhon, is also mentioned as one of his companions.

Ares is inserted among the fabulous kings of Manetho. Vettius Valens says that the planet Mars was called by the Egyptians *Artes;* and Cedrenus makes the name *Ertosi.* Herodotus tells us that Mars was worshipped at Papremis.

Somus, or *Shom*, was probably the personage called the Egyptian Hercules by the Greek writers. Thus, the great Etymologicon has *Chon* for this deity, and Eratosthenes writes his name *Sem*, both of these having been probably intended to express the Coptic JOM or SJOM, *strength*, which seems sometimes to have been written JEM or SJEM. Diodorus mentions this Hercules as a general of Osiris, whom he left behind with Isis. He is said to have been killed by Typhon, but to have been revived by the smell of a quail. Herodotus asserts that the word Heracles is originally Egyptian; but in this, as in many other instances, his interpreters must have misinformed him, perhaps from misunderstanding his questions; for his Egyptian etymologies are almost uniformly erroneous. Thus, when the priests had shown him, or rather Hecatæus, whose original story he seems to have copied and disfigured, the statues of three hundred and forty-one successive generations of high priests, who were neither gods nor heroes, but each a PIROMIS, the son of PIROMIS, he tells us that PIROMIS means *beautiful and brave;* whilst, in fact, the literal sense of PIROMI, in the modern Coptic of Lower Egypt, which is simply *a man*, restores to the observation of the priests an intelligible and consistent sense.

Buto, the nurse of Horus and of Bubastis, compared to the Latona of the Greeks, must be considered as anterior to the birth of Horus.

Horus, *Hor*, *Or*, or *Horsiêsi*, was the son of Isis and Osiris. Jablonsky observes that a king *Ur* is mentioned by Manetho, and that *Or* was in later times the name of a certain monk, and *Taor* of a nun; the Egyptians have always, as Lucian informs us, had a propensity to adopt the names of their deities for their own, so that they may have become current in families without any immediate reference to their origin. Akerblad also found *Horsiêsi* as an Egyptian name, and conjectured, with much probability, that it originally meant Horus the son of Isis, SI being an abridgment of SHERI, as it appears also to have been in the name of *Siphoas*, or rather *Siphthas*, which is explained by Eratosthenes, *the son of Vulcan.* Horus is often confounded with the Sun, perhaps from the resemblance of his name to the Hebrew AOR, *light;* whilst Suidas makes him rather analogous to Priapus. He was nursed by Buto, in the city Butus. The most remarkable exploit of his youthful days was the pursuit and conquest of Typhon, in revenge for his father's death. The constellation Orion was supposed to be the habitation of his soul. His dress was white. Damascius, as copied by Photius, informs us that he was represented with his finger on his mouth.

Harpocrates was a son of Osiris, from a visit paid to Isis after his death. He was also born prematurely, and was weak in his lower limbs. Eratosthenes seems to have called him Phrucrates; and PHROKHRAT, in Coptic, means *dried* or *withered feet.*

Anubis was the offspring of Osiris and Nephthé, whom he had mistaken for Isis, and who exposed the child; but Isis recovered him, and he became her faithful attendant. He was considered as belonging both to the upper and the lower worlds, and was therefore compared to the horizon; and he seems to have been typified by a dog, or figured with a dog's head. He attended Osiris in his military expedition; and he is sometimes erroneously confounded with Mercury, and even with Saturn. A cock was usually sacrificed to him; and Pliny tells us that his images were properly made of gold, in allusion to his name; a remark which is amply explained by the Coptic word NUB, which still signifies *gold.*

Arsaphes is mentioned by Plutarch as a son of Isis; but the same name is said to have been sometimes applied to Osiris.

Athor, *Hathôr*, or *Athyr*, was the Venus of the Egyptians, according to the Great Etymologicon. Herodotus mentions a temple of Venus as Atarbechis, which might be translated the city of Venus, BAKI in Coptic meaning city; although Plutarch enumerates Athyri among the different names of Isis. Strabo informs us that at Momemphis a sacred cow was fed in honour of Venus.

Amun, or *Amoun*, the Jupiter of the Egyptians, though apparently a personage of much less importance than the Greek and Roman Jupiter, was worshipped by the Ammonians, under the form of a human figure with a ram's head. Hecatæus, as quoted by Plutarch, denies that this term is the proper name of the deity, and observes, very truly, that it is an Egyptian word meaning *come*, by which the god was supplicated to appear. The word, however, implies also *glory*, or *splendour*. If there was a more appropriate term for this deity, it may possibly, as Mr Akerblad has observed, have been *Ho*, which was the Egyptian name of the city called by the Greeks Diospolis Parva. It is remarkable that Manetho gives us a Zeus distinct from Ammon, interposing Tithoes and Sosus as intermediate kings.

Antæus, *Entes*, or *Mendes*, is said to have been left by Osiris as a viceroy or lieutenant-governor, together with Busiris, for the assistance of Isis during his absence. He is generally identified with Pan, though Diodorus mentions Pan as having accompanied Osiris on his expedition. At Mendes a goat was fed in honour of this deity, and Plutarch seems to say that this goat was called Apis, as well as the bull fed at Memphis. He was also generally represented with the face and legs of a goat. Herodotus calls him one of the eight gods, older than the twelve; but Diodorus makes the eight senior gods of the Egyptians the Sun, Kronos, Rhea, Ammon, Juno, Vulcan, Vesta, and Mercury. Out of these, however, Juno and Vesta cannot easily be identified in the Egyptian mythology.

Busiris, a name composed of *B-Ousirei*, or *Ph-Ousirei*, that is, Osiris with a prefix, is only mentioned by Diodorus as a colleague of Antæus in his government.

Macedon, according to Diodorus, was a companion of Osiris in his expedition.

Bubastis was a sister of Horus, preserved and nursed with him by Buto in the city of Butus. She is compared by various authors to Artemis or Diana; Apuleius gives us Bubasthis for the Egyptian name of the plant Artemisia; and Bubastis is addressed in a Greek epigram in the place of Diana, considered in her obstetrical capacity.

Sarapis, an ancient deity of the Greeks, was raised into a more distinguished rank by the honours paid him, as identical with Pluto, by Ptolemy Soter, who had found an image of Pluto at Sinope, accompanied by Cerberus and a dragon, which he brought to Alexandria, and established in the Serapeum there, as belonging to Sarapis. Some of the ancients were however of opinion that the word Sarapis meant only the "feast of Apis;" and, indeed, the Coptic SHAIIRI, which signifies to feast, agrees tolerably well with this etymology, however improbable the opinion founded on it may be esteemed. Sarapis is also supposed to have had some relation to the regulation of the Nilometer, which consisted of a column with different heights marked on it, in the centre of a bath or well, into which the water of the river was admitted.

Esmunus, or *Shmun*, was the eighth son of Sadycus by one of the Titanides, and brother of the Dioscuri and Cabiri; all of them names which seem as foreign to the Egyptian mythology as the word SHMUN is familiar to the language, meaning simply *eight*. He is, however, said by Damascius to have been the Egyptian Æsculapius, although Manetho gives the name Tosorthrus to this deity, making him a son of Pan and Hephæstobule.

Paamyles is mentioned by Hesychius and Plutarch as a Priapic deity; he is also made by Cratinus synonymous with *Socharis.*

Tithrambo, according to Epiphanius, was analogous to the Hecate of the Greeks.

Thermuthis, though generally understood to be only a name of the sacred serpents worn in the crown of Isis, is distinguished by Epiphanius as an independent deity; and if we may judge by the signification of the Coptic word, which means *mortiferus*, her character must have been somewhat analogous to that of Nemesis.

Canopus, or *Canobus*, had a temple which is mentioned by Dionysius Periegetes. The jars called Canopi were often made porous, to serve as filters, and are mentioned by Hesychius, in the word *Stactice;* but we are not exactly informed how far they were connected with this deity.

Menuthis was the wife of Canopus, and seems to have given her name to a village near the town Canopus, which is mentioned by Stephanus. Epiphanius calls her *Eumenuthis.*

Besa is only known from Ammianus Marcellinus, who mentions an oracle dependent on him.

Proteus, though noticed as a king of no very high antiquity, is said to have had a temple erected to him as a hero. Diodorus says that his Egyptian name was Cetes; though Herodotus, as in other instances, fancies, from some misapprehension, that the Greek and Egyptian names were identical; and he observes that similar honours were also paid to Perseus, another hero known to the Greeks.

Nilus, whether as a king or merely as a river, appears to have received divine honours. The Egyptian name of the Nile seems to have been simply PHIARO; the Ethiopians call it *Siris;* the AMEIRI of Kircher's vocabulary was probably a name of later date.

Apis, a bull consecrated to Osiris, was fed with divine honours at Memphis, the principal burying-place of that deity, of whose soul he was considered as the living image. He was all over black, except some small white spots, and some other particular marks not of common occurrence. He was sometimes said to be the offspring of a cow and a ray of moonlight.

Mneuis, or *Mnyis*, was also a black bull sacred to Osiris, kept at Heliopolis; although some authors assert that he was sacred to the sun. Ælian mentions also a black bull called Onuphis; and Macrobius speaks of a bull named Pacis, or Bacis, which was kept at Hermonthis. For the cow that was consecrated to Venus it does not appear that any particular name has been recorded.

SECTION VII.

OF THE EGYPTIAN CALENDAR.

Importance of the subject.—Its connection with the system of mythology.—Authorities.—Testimony of Eratosthenes.—Year of the Greeks of Alexandria no other than the Julian year.—Commencement of the ancient or moveable Egyptian year.—Sun's place in the zodiacal signs.—Consequences deduced therefrom.—Conditions of determining the date of a monument from the astronomical symbols.—Zodiacs of Esneh and Denderah.—Date of the latter.—Form of the sign Libra in the zodiac of Esneh.—Explanation of the beetles in the zodiac of Denderah.—No astronomical records of importance discovered, or perhaps discoverable, in hieroglyphical literature.—The months of the fixed or Alexandrian year.

From the mythology of Egypt we pass to the consideration of its calendar, which, besides being intimately connected with its system of religion, has often been a subject of speculation both with critics and with astronomers. The inquiry is no doubt in itself somewhat intricate; but the principal difficulties have arisen from the ignorance or carelessness of the Greek authors who have written on the Egyptian mythology. The Baron Alexander von Humboldt and M. Jomard have displayed great learning and research in collecting authorities on this subject; and nothing is wanting to establish the propriety of their acquiescence in the opinion of Petavius, except a little less indulgence for the extreme inattention of Plutarch, and a more marked deference to the important testimony of Eratosthenes, a writer whose catalogue of the Egyptian kings has already been noticed as bearing intrinsic marks of the authenticity of his information, and whose competency, as an accomplished astronomer, to discuss the regulation of the calendar, is of still greater notoriety. Geminus, a Greek astronomer of the Augustan age, has very distinctly stated that the later Greeks had been in the habit of mentioning the Egyptian festivals as connected with particular seasons of the year, in spite of the clearest evidence that their mythological year consisted of 365 days only, and that their anniversary festivals must necessarily have passed in succession through every part of the natural year. "It is a common and inveterate error among the Greeks," says Geminus, "to believe that the festival of Isis happens at the winter solstice. This was indeed true a hundred and twenty years ago, but it is now a month earlier; and such a mistake betrays the grossest ignorance of the Egyptian calendar. In former ages this festival was celebrated not only as late as the winter solstice, but, at an earlier period of time, even at the summer solstice; as Eratosthenes expressly states in his *Commentary upon the Octaeterides.*"[1]

The later inhabitants of Lower Egypt, and especially the Greeks of Alexandria, had certainly a stationary as well as a wandering year; but this was no other than the Julian year, which was introduced here some little time after its establishment in other parts of the Roman empire, and which was probably the only year ever employed by the Coptic Christians, although it can scarcely have been adopted at any time by the Pagan Egyptians. The common opinion is, that the Julian calendar was established at Alexandria in the year twenty-five before Christ, the first month Thoth then beginning on the 29th of August, as the Coptic year continued to do ever after. Thus Vansleb found, in the seventeenth century, that Thoth began on the 8th of September new style, which was the 29th of August old style. A passage of Theon, in his *Commentary on Ptolemy*, would rather incline us to fix on the 1st September for the beginning of the Alexandrian year; but the ecclesiastical authority is more direct, and it is confirmed by the present usage of the Abyssinian church. The quadriennial intercalation of a sixth supplementary day took place, according to the Abbé Boyer, at the end of the second year after the Julian bissextile; so that, in the year preceding the bissextile, the first of Thoth happened on the 30th of August. From these authorities we have no difficulty in ascertaining the beginning of the ancient or moveable Egyptian year for any earlier or later period; reckoning both ways, for the sake of simplicity, in Julian years.

B. C. 1500	2d Sept. O. S.	B. C. 400	1st Dec.
1400	8th Aug.	300	6th Nov.
1300	14th July.	200	12th Oct.
1200	19th June.	100	17th Sept.
1100	25th May.	B. of C.	23d August.
1000	30th April.	100	29th July.
900	5th April.	200	4th July.
800	11th March.	300	9th June.
700	16th Feb.	400	15th May.
600	21st Jan.	500	20th April.
500	26th Dec.		

It is of importance, in the discussion of some representations of astronomical objects, to determine at what time of the year the sun entered the respective signs, according to the Egyptian calendar, or, more particularly, what was the sun's place in the starry zodiac at the commencement of the year for different periods of time. Taking, then, 6h. 9m. 8s. for the excess of the sidereal above the Egyptian year, we find that 1424 Julian years were required for a complete revolution of the sun's place on the first Thoth, and 119 for each sign. Now since, about a century before the establishment of the Julian calendar, the sun entered Libra on the 24th of September, and since the Egyptian year began on that day, in 120 before Christ, it follows that Libra had been the first constellation during the whole of the preceding century; for, at this period, the beginning and end of the signs of the ecliptic agreed very nearly with those of the corresponding constellations of the zodiac. The first constellation of the Egyptian year will therefore stand nearly thus:

From 1552 B. C.		484	♑
to 1433	♍	365	♐
1314	♌	247	♏
1196	♋	128	♎
1077	♊	9	♍
958	♉	A. C. 110	♌
840	♈	228	♋
722	♓	347	♊
603	♒		

We may take, for an example of an Egyptian date, that of the Rosetta stone, in the ninth year of Ptolemy Epiphanes, or 196 before Christ, when the Egyptian year must have begun on the 11th of October; consequently the first of the sixth month, Mechir, was the 9th of March, and the 18th of Mechir, which is made synonymous with the 4th of Xanthicus, the 26th of March; so that Xanthicus must constantly have begun on the 22d of March, if the intercalations were properly adjusted; and this agrees sufficiently well with Usher's table of the Macedonian lunar months, which may therefore be supposed to have been generally employed by the Greeks in Egypt.

If we attempt to determine the date of a given monument from astronomical symbols contained in it, we must suppose that they represented the state of the heavens with respect to the Egyptian year at the time in question. Thus, in the zodiacs of the ruins at and near Esneh or Latopolis, the constellation Pisces seems to be the first sign, as it really was, about 800 before Christ, or in the time of Bocchoris and of the Ethiopian dynasty. It is, however, equally possible that Virgo may have been intended for the first sign, and this would answer either to the century immediately preceding the birth of Christ, or to a period fourteen centuries earlier. The zodiac at Denderah appears to begin with Leo; and unless we suppose its antiquity extravagantly great, we must refer it to the time of Tiberius, as Visconti has indeed already remarked. Mr Hamilton has confirmed this opinion by the collateral evidence of inscriptions in honour of the Roman emperors; although, with respect to the difference of time implied by the difference of a sign in the beginning of the zodiacs, he is rather inclined to adopt the sentiments of Lalande, who refers it to the effect of the precession of the equinoxes; imagining, without any kind of authority, that the division of the signs corresponded to the period of the solstices, a period which never constituted a marked feature in the Egyptian calendar.

In the zodiac at Esneh the sign Libra is denoted, as is usual in the Roman representations, by a female holding the balance; whilst the Egyptian constellation, in most other instances, is without the female. Servius, however, informs us that the Romans borrowed this sign from the Egyptians, the Greek astronomers having considered it as a part of the Scorpion; so that there is no reason to question the antiquity of the ceiling, from the occurrence of this constellation in it. The sign Cancer, both here and elsewhere, has eight feet, and it has certainly no connection with the figure of the sacred beetle, which occurs many thousands of times in other places, but never with more than six feet.

The beetles in the zodiac of Denderah have a very different signification, and the whole representation is much more of a mythological than of an astronomical nature. The beetle near the beginning of the zodiac is the well-known symbol of generation, and he is in the act of depositing his globe. On the opposite side, at the end of the zodiac, is the head of Isis, with her name, as newly born; both the long female figures are appropriate representations of the mother; and the zodiac between them expresses the "revolving year" which elapsed between the two periods. This explanation is completely confirmed by a similar representation of two female figures on the ceiling of the first tomb of the kings at Biban-el-Molouk; one with the beetle, and the other with the name of the personage just born. Between them, instead of the zodiac, are two tablets, divided into 270 squares, or rectangles, corresponding to the number of days in nine Egyptian months, with ten circles placed at equal distances, probably intended to represent full moons, and relating to the ten incomplete lunations to which these days must belong. The number 270 is too remarkable to be supposed to have been introduced by mere accident; and when the argument is considered as a confirmation of other evidence, in itself sufficiently convincing, the whole must be allowed to be fully conclusive.

---

[1] Geminus *in Petavii Uranologia*. Par. 1630, f. p. 33.

There is indeed little chance of our discovering any astronomical records of importance among the profusion of hieroglyphical literature which is still in existence. Herodotus tells us that the Greeks derived their acquaintance with astronomy from the Babylonians, though they were supposed to have learned the elements of geometry from the Egyptians; and it is well known that Ptolemy the astronomer, who lived at Alexandria, and who, as well as Eratosthenes before him, must have had easy access to all the knowledge of the Egyptian priests, refers to no Egyptian observations, but employs the Babylonian records of eclipses which had happened a few centuries before his time; records which, as Pliny informs us, were preserved on a particular kind of bricks, the same, perhaps, which have been brought to Europe in our own times, as undeciphered specimens of the nail, or arrow-headed character. But a certain degree of geometrical knowledge can scarcely be denied to a people who had made very considerable progress in sculpture and architecture, at a time when all Europe was immersed in the profoundest barbarism, and who must necessarily have had frequent occasion for the employment of agrarian measurements. The Egyptians must also have been good practical chemists; so far, at least, as was required for the preparation of brilliant, diversified, and durable pigments; and even their devotion to alchemy, which derives its name from having been the *secret* or *dark* study of Egypt, must have led them to make some little progress in experimental philosophy, although neither their manufacturers nor their magicians could have any right to boast of solid acquirements in genuine science.

The months of the fixed or Alexandrian year were these:—

1. Thoth,	began 29th August, O. S.
2. Paophi,	28th September.
3. Hathôr, Athôr, or Athyr,	28th October.
4. Choiak,	27th November.
5. Tobi,	27th December.
6. Mechir,	26th January.
7. Phamenoth,	25th February.
8. Pharmuthi,	27th March.
9. Pashon,	26th April.
10. Paoni,	26th May.
11. Epiphi,	25th June.
12. Mesori,	25th July.

The years are commonly dated from the era of the martyrs of Diocletian, beginning in the autumn of 284.[1]

SECTION VIII.

REMARKS ON VARIOUS PUBLICATIONS RELATING TO EGYPT.

General observations.—French national work.—Hamilton's Egyptiaca.—Travels of Ali Bey, or Senor Badia.—Legh's Narrative.—Captain Light's Travels.—Mr Walpole's Collection of Memoirs relating to European and Asiatic Turkey.—Journal of Dr Hume.—Colonel Leake's Map of Egypt.—Quarterly Review.—Captain Caviglia; his labours and researches.—Mr Belzoni; his discoveries in the catacombs at Biban-el-Molouk, and in the Pyramid of Cephrenes.—Mr Salt and Mr Bankes.—Sheikh Ibrahim (Burckhardt); his travels and researches in Nubia.—Mr Cailliaud.—Discovery of Berenice.—The Egyptian Society.—Its collection of hieroglyphics.—Trilingual or trigrammatic stone of Rosetta.—First attempts made to decipher its triple inscription.—Reference to the article HIEROGLYPHICS.

By reason of the very early progress which the inhabitants of Egypt had made in the arts of civilized life, the antiquities and literature of that country have always been considered as objects of the highest interest and curiosity, though involved in inextricable obscurity; but we have acquired, in the course of the last thirty years, and are still continuing to acquire, such additional information respecting them as promises, if completely confirmed by future researches, to establish the whole of our knowledge respecting this marvellous country on a new and a sure foundation.

The labours of the French Institute at Cairo have been communicated to the public in a work of unexampled splendour and magnificence, the *Déscription de l'Egypte*, which was some time ago completed at the cost of the government. Many of the monuments brought by the British army to England have also been accurately and elegantly engraved in this country; and a variety of travellers of different nations have published accounts of their numerous observations and discoveries made in Egypt and the neighbouring countries.

The first in order of these that it will be necessary to notice is Mr William Hamilton's volume, entitled *Remarks on several parts of Turkey*, Part i. *Ægyptiaca.* London, 1809, 4to. It appears that the power of the French in Egypt having terminated in September 1801, the temporary possession of the country was at first divided between the Turks, the Mamlukes, the Arabs, and the English, a circumstance which afforded some convenience to a European traveller, although it had no tendency to enlarge the sphere of his observations. In the beginning of October, Captain Leake and Lieutenant Hayes were appointed by General Hutchinson to make a general survey of Egypt, and of the country beyond it, if it should be found practicable to penetrate farther south. Mr Hamilton, who had resided at the British head-quarters for the purpose of corresponding with Lord Elgin upon the events of the war, was now at liberty to join these gentlemen in their expedition; and the various information which, with their assistance, he collected, respecting the remains of the ancient Egyptian magnificence, bears ample testimony to the good taste, as well as to the industry and accuracy of the whole party. On account, however, of the disturbed state of the country, and of a multitude of other difficulties, both moral and physical, they were unable to proceed farther south than a few hours' journey beyond Syené, to a village called Debôd, opposite to which they observed the ruins of Barembre, the Parembole of the ancients, among which they found a Greek dedication of a temple to Isis by Ptolemy Philometor and his queen. They also collected a variety of inscriptions from other parts of Egypt, to which they added drawings and descriptions of the remains of the buildings to which they belonged; and, at Alexandria in particular, Mr Hamilton was enabled, in company with some other gentlemen, by examining the inscription on Pompey's pillar in different positions of the sun, to ascertain the name of Diocletian as that of the emperor to whom it was dedicated, and also to detect some traces of the name of Pompeius, who has been shown by M. Quatremère to have been a prefect of Egypt under that emperor. It is to be regretted, however, that the Coptic inscriptions, which are sometimes found mixed with the Greek, have not been more generally copied by travellers.

---

[1] For much valuable information, laboriously collected and clearly digested, respecting the peculiarities of the form of year used by the ancient Egyptians, more especially as regards the influence which these peculiarities are supposed to have exercised on their modes of calculating and recording the dates of their civil history; and also for some very original and ingenious speculations concerning the primitive form and probable origin of the Egyptian calendar, astrological as well as civil, together with an examination of the period and circumstances of the first introduction of the zodiac into Greece; the reader may consult *A Dissertation on the Calendar and Zodiac of Ancient Egypt*, by W. Mure, Esq.; a work which, from the learning and research embodied in it, no less than from the novelty of some of the speculative views it unfolds, will amply repay the most attentive perusal.

Señor Badia, a Spaniard, who is supposed to have been sent into the East on the business of the French government, published two volumes of his *Travels*, under the name of *Ali Bey*. They embody some documents relating to the recent history and present state of Egypt, but contain very little information respecting its antiquities.

Mr Legh and Mr Smelt visited Egypt in 1812. They extended their tour as far as Ibrim, and observed in their way many remains of ancient buildings, some of which were in perfect preservation; but they were unable to attain the second Cataract, which was said to be three days' journey farther south.

Besides some other interesting antiquities which he collected, Mr Legh obtained in the island of Elephantiné a few Thebaic manuscripts, written with a chalybeate ink on skins of leather, which he afterwards deposited in the British Museum. They appear to be principally conveyances of estates, dated at Cyrshe or Gyrshe, a place fifty or sixty miles beyond Assouan or Syené; and, though unimportant in themselves, they tend to illustrate the history of the kingdom of Nubia in the middle ages. This kingdom seems to have been almost forgotten by some late travellers and geographers, although it was formerly remarkable for having been, according to an old tradition, one of the first that embraced Christianity, even in the time of the Queen Candace, one of whose servants was baptized by St Philip,[1] and who appears to have been one of the immediate successors of the Candace mentioned by Strabo as having attacked the province of Egypt, and having been conquered by Petronius in the time of Augustus. The kingdom of Nubia extended as far north as Syené, which continued to be the boundary of the Mussulman power in the tenth century, and probably much later. To the south it originally comprehended Ethiopia, its capital Meroë being placed in latitude 17°, on an island in the Nile, or rather on a peninsula formed by its principal branches. Candace had also a palace at Napata, which Pliny makes about five hundred Roman miles beyond Syené, and three hundred and sixty short of Meroë. In the seventh century, the Nubians seem nominally to have been made tributary to the Arabs; but they remained in fact almost wholly independent of them in their government, and their religion was entirely subjected to the spiritual direction of the patriarchs of Alexandria. Early in the tenth century the Nubians attacked Syené, not as rebels, but as legitimate enemies. They were, however, repulsed soon afterwards. A little later we find that George, king of Nubia, was a mediator between the king of Abyssinia and the patriarch, whom he persuaded to send bishops from Alexandria into Ethiopia. In the eleventh century, Solomon, king of Nubia, abdicated in favour of his nephew George, and retired to a monastery, within three days' journey of Syené; whence he was brought by the Saracens to Cairo, and there treated with great attention as a sort of state prisoner. It is also said that a king Cyriac once raised a hundred thousand men to assist the Christians against the Mussulmen; but the magnitude of the number renders the whole story more than doubtful. We learn from Hartmann's notes on Edrisi, that Abulfeda in the fourteenth century, and Bakoui in the fifteenth, spoke of the Nubians as still Christians; and it seems highly probable that they continued to exercise their religion till about the time of Sultan Selim in the beginning of the sixteenth century, if not still later; for Vansleb, who was at Siout in 1673, tells us that the churches were then still entire, though they were shut up, Christianity having become completely extinct for want of pastors. He gives us the names of seventeen bishoprics, which had constituted three provinces: the first province he calls Maracu, and attributes to it the bishoprics of Korta, Ibrim, Bucoras, Dunkala or Dungala, Sai, Termus, and Scienhur; the second province seems to hold a middle place; and in the third he mentions Soper as the capital of the kingdom, without noticing Nuabah, which is the name given to the metropolis by the Arabic authors. D'Herbelot, who died in 1695, speaks of the patriarch still resident at Dongola, and appointed by the patriarch of Alexandria. At any rate, there can be little doubt that the "King John" mentioned in the manuscripts of Gyrshe as a Christian must have been a king of Nubia, and rather a predecessor of the Mek of Dongola than a Greek emperor, whose authority was probably never acknowledged in this country, and least of all when Egypt was in the possession of the Arabians.[2] The remains of the churches mentioned by Vansleb were observed in many parts of Nubia, by Captain Light of the Royal Artillery, covered generally with paintings of scriptural subjects, and not uncommonly appearing to have been originally built for pagan temples. At Dakké Captain Light found the name of Hermes inscribed as that of the deity to whom the temple situated there must have been dedicated; and it will be interesting to inquire if any hieroglyphics can still be found on this remarkable edifice, which will bear a similar interpretation.[3] More recently Captain Light published a separate volume of his *Travels*, London, 1818, 4to.

Mr Walpole's collection contains also some older papers by Mr Davison, who was British consul at Algiers, and accompanied Mr Wortley Montague to Egypt in 1763. Mr Davison, as already stated, discovered in the Great Pyramid a room before unknown, immediately over the chamber which contains the sarcophagus; and he descended the three successive wells to the depth of a hundred and fifty-five feet. He also described the catacombs of Alexandria, which seem to have been principally employed by the Greek inhabitants of that city. The same volume contains a very interesting account of the customs and manners of modern Egypt, from the journal of Dr Hume.

Byzant.* vol. xxi.; *Ancient Universal History*, fol. vol. vii.; *Modern Universal History*, vol. i.; Vansleb. *Hist. de l'Egl. d'Alexandrie*, Par. 1677, p. 29; D'Herbelot, *Bibl. Orient.*; *Narrative of a Journey in Egypt, and the Country beyond the Cataracts*, by Thomas Legh, M. P. 4to, Lond. 1816; *Sepulchral Inscriptions from Nubia*, Archæologia, xix. p. 169.

[3] *Memoirs relating to European and Asiatic Turkey*, edited by R. Walpole, M. A. 4to, Lond. 1817, p. 402. 465.

A considerable addition has been made to our knowledge of the geography of Egypt by the publication of Lieutenant Colonel Leake's accurate and elegant map of that country, comprehending also a sketch of Nubia, as far as the southern Cataract, which appears to be the limit of the existing remains of antiquity. Besides the results of his own personal survey, Colonel Leake has employed the observations of the French astronomers for the determination of the situation of the different places; and, with respect to the remoter parts, he had the advantage of consulting the manuscript papers of the lamented Mr Burckhardt, who unhappily fell a victim to a dysentery at Cairo in October 1817, after having obtained, by a long residence in the country under the name of Sheikh Ibrahim, an intimate acquaintance with every thing that could have tended to facilitate the further prosecution of his projected expedition into parts of the continent still more remote. Besides the ruins of Greek churches scattered throughout this country, the principal points of Nubia, which are remarked as exhibiting remains of still greater antiquity, are the Parembole of the Itinerary of Antoninus near Debôd, and Tzitzi, now Klitzie, both of which had been visited by Colonel Leake and Mr Hamilton; Kardassy or Gartaas; Taphis and Contra Taphis, now Tafa; Kalabshé, the ancient Talmis; Merowan, the ancient Tutzis, near Gyrshe; Pselcis, now Dakké and Corte, still Korti; Maharraka, supposed to be the Hierosycaminon of the Itinerary, and which may very possibly have been the Maracu mentioned by Vansleb as an archbishopric; Seboua; Hasseya; Derr; Ibrim, the Premnis of the ancients; Ybsambul, perhaps the Aboccis, with its two temples, still better known by the labours of the active and ingenious Belzoni; Beyllany, or rather Fereyg; Serra, probably Phthuris; Sukkoy, perhaps Cambusis; Samne, not improbably the Acina of Nero's spies; Aamara, possibly Stadysis; and Soleb, not far short of the southernmost Cataract, where the author is disposed to place the Napata of the ancients, in latitude about $19\frac{1}{2}$°. This situation would agree very well with the distances of Napata from Syené and from Meroë; but it is impossible to admit that this Cataract can be so far south as even 20°, consistently with the testimony of other geographers respecting the latitudes of Mosho and Sukkot; and indeed the course of the river is laid down more nearly north and south than the description of Burckhardt requires.[1]

The *Quarterly Review*, in various numbers, afforded a highly interesting and gratifying detail of the operations and discoveries which had been conducted in Egypt by several of our spirited and enterprising countrymen. Amongst these Mr Bankes proceeded the farthest south in the steps of Mr Burckhardt, and made collections and drawings of a great number of striking remains of antiquity;[2] and he sent home to this country a variety of statues and bas reliefs, as well as large manuscripts on papyrus, in the epistolographic or enchorial character. Mr Salt was also indefatigable in his exertions, and he most fortunately found an assistant of Herculean strength of body, and of proportional energy of mind, in the person of Mr Belzoni. The head called a young Memnon, now in the British museum, which weighs eight or ten tons, and which is one of the very finest specimens of Egyptian sculpture extant, was a joint present of Mr Salt and Mr Burckhardt; and Mr Belzoni, as already stated, had the merit of having conducted the very difficult operation of bringing it down to the Nile. Mr Hamilton conjectured that it might have belonged to the statue described by Philostratus as a Memnon of great beauty;[3] but the remaining fragment of the hieroglyphical inscription agrees better with the name of another sovereign, apparently of the same family, who is represented in several other magnificent monuments at Thebes and elsewhere.

Captain Caviglia, the master of a mercantile vessel in the Mediterranean, exerted himself with singular activity and perseverance in examining the interior of the great pyramid of Cheops. After having retraced the forgotten steps of Mr Davison, he succeeded in pursuing the principal oblique passage two hundred feet farther downwards than it was before practicable, and in discovering at this point a communication with the well, which descends from the floor of the upper chamber. This communication affording him a freer circulation of air, he was enabled to proceed twenty-eight feet farther in the passage, when he found that it opened into a spacious chamber, sixty-six feet by twenty-seven, but of unequal height, immediately under the centre of the pyramid, which Mr Salt supposes to have been the place of the *theca*, or sarcophagus, mentioned by Strabo as situated at the end of the oblique passage, though at present no sarcophagus is to be found in it. The floor is elevated thirty feet above the level of the Nile, so that the water could never have flowed into this part of the pyramid, to surround the tomb of Cheops, as Herodotus imagined. Some passages leading out of this chamber appear to terminate abruptly, without opening into any others. The dimensions of the upper chamber, which still contains a sarcophagus, are only thirty-five and a half feet by seventeen and a quarter, and eighteen and three fourths high.

Captain Caviglia having proceeded to examine a number of detached mausoleums, more or less dilapidated, in the neighbourhood of the pyramids, found their embellishments chiefly in the style of the Theban catacombs; and, what is not a little remarkable, they sometimes contained images too large to have been brought in through the doors or windows. Some of the stones with sculptures were placed upside down; and it was conjectured that these might possibly have been portions of the original casing of the pyramids, which is said to have been sculptured, but which is now fallen down. His next undertaking was the very arduous task of digging away the sand in front of the great Sphinx; a share of the expenses of this labour, which amounted to eight or nine hundred pounds, being contributed by Mr Salt and some other gentlemen. The body of the monster is principally formed out of the solid rock, and the paws are of masonry, extending forwards fifty feet from the body; between them were found several sculptured tablets, so arranged as to constitute a small temple or chapel; and farther forwards a square altar with horns, which seems to have been employed for burnt offerings.

Mr Belzoni, after many fruitless efforts, succeeded, as already mentioned, in discovering the entrance into the second pyramid of Cephrenes, in which Herodotus had asserted that there were no chambers. An Arabic inscription testifies that the pyramid had once been opened in the presence of the "Sultan Ali Mahomet the First, Ugloch," who may possibly have been the Ottoman emperor, Mahomet the First, in the beginning of the fifteenth century.[1] Among the Theban catacombs Mr Belzoni discovered six new tombs; the most remarkable of which, with all its galleries, three hundred and nine feet in length, he called the tomb of Apis, from having found the mummy of a bullock in one of its chambers. In another apartment was the magnificent sarcophagus of white alabaster already mentioned; and the whole excavation, sculptured and painted in the most finished style of art, was found in the most perfect preservation. In Nubia the spirit and perseverance with which the little band of excavators pursued the attempt to penetrate into the temple of Ybsambul were not less worthy of admiration. Mr Belzoni and his servant, accompanied only by Mr Beechey, were abandoned on some futile pretence by the Arab workmen whom they had employed, and were unable to procure for many weeks any other food than dhurra or millet. They had resolution enough, however, to proceed with their enterprise as manual labourers, and they were at last amply rewarded for their perseverance. In front of the temple there were four colossal statues, sixty feet high, one of which had been thrown down; but it was only after digging for three weeks, through a hundred and fifty feet of sand, that our adventurers succeeded in entering the temple, consisting of fourteen chambers and a great hall, cut out of the solid rock, and ornamented with sculptures superior in point of execution to the greater part of those which are found in Egypt; besides eight colossal statues thirty feet high, which are placed in the hall. Mr Belzoni also found at Thebes a colossal head and arms, supposed to have belonged to a Horus; and his lady discovered, during his absence in Nubia, a fine statue of white marble, supporting a ram's head on its knees.

[1] *Map of Egypt*, two sheets, Lond. 1818.

[2] *Quarterly Review*, No. 31.

[3] *Ibid.* No. 36.

Though Burckhardt's untimely end interrupted his farther progress in Africa, yet with respect to Nubia his observations were complete, and he had himself prepared his journals for publication, in a form which does equal credit to his diligence and judgment in observation, and to his candour and good taste in the simple and elegant narration of that which he had observed.

It appears that the Nile, between the first and second Cataracts, runs chiefly through a country of sandstone, and is navigable throughout this extent; but at the Cataract of Wady Halfa, a little above Ybsambul, the sandstone terminates, and the district of granite and other primitive rocks begins, extending a hundred miles farther upwards; and in this space the course of the river is interrupted by frequent shallows and small falls. The roaring of the fall at Wady Halfa may be heard at the distance of a mile or two; but the part of the river that falls is only about twenty yards over. There are, however, three falls in succession, and the neighbouring scenery is very romantic. Immediately beyond this country is Kolbe, the principal place in the district of Sukkot, for there is no town of that name; then the island Say, probably the Sai of Vansleb; and four hundred and fifty miles above Assouan, according to Mr Burckhardt's reckoning, is Tinareh, in the district of Mahass, the farthest point to which he penetrated, within fifteen or twenty miles of the remotest Cataract, and a day and a half's journey only from Mosho by the shortest road. The country through which he passed was supposed to contain a population not exceeding a hundred thousand, and governed by three Kashefs, who are brothers, and tributary to Egypt, but inclined to favour the Mamlukes, who were established in the neighbourhood of Dongola. At Mahass a series of more than twenty little kingdoms begins, which extend to Sennaar. At Mosho begins the kingdom of Dongola; and near the same place is the island of Argo, a whole day's journey in length, with a brick castle in it. There are many other islands in the course of the river through Dongola, which extends for five days' journey. The country is celebrated for a very fine breed of horses, like the Arabian, but much stronger, and fed, as Bruce observed of the horses in the same neighbourhood, on straw only. The city of Merawe, singularly resembling the ancient Meroë in name, is the metropolis of the Sheygya Arabs, beyond Dongola, and is remarkable for schools of high reputation, which are particularly celebrated for their penmanship.

The languages spoken in Nubia are the Kensy and the Nouba, the former of which was confined to the northernmost parts of the country. These languages somewhat resemble each other, but they differ essentially from the Arabic, although the people are supposed to be the descendants of Bedouin Arabs, who spread from the East in the middle ages, with the exception of a few of the original inhabitants, who remain about Tafa and Serra, having become Mahommedans. But however this may be, it is certain that the languages exhibit no traces whatever of any dialect of the old Egyptian; and this circumstance affords a very strong argument in confirmation of the author's assertion, that the Christians had in general been expelled from Nubia before the time of Sultan Selim; the three garrisons of Bosnian soldiers, whom this prince established in Assouan, Ibrim, and Say, having been sent by the express invitation of one of the rival factions of Arabs, who occupied the country, and remaining still distinct from the rest of the population, and being governed by their own Agas. We can only reconcile these facts with the testimonies in favour of the existence of Christianity in Nubia down to about the same time, by supposing that its extinction must have been gradual, and that the Thebaic language, and the ancient religion of the country, dwindled away by degrees, not for want of pastors only, but from the hostility of the Arabian intruders.

A concise but clear and satisfactory description of the various temples noticed in Colonel Leake's map, is inserted in the relation of Mr Burckhardt, who conjectures that the order of their antiquity is nearly this: 1. Ybsambul; 2. Gyrshe; 3. Derr; 4. Samné; 5. Ballyané; 6. Hasseya; 7. Seboua; 8. Aamara and Kalabshé; 9. Dakké and Maharraka; 10. Kardassy; 11. Merowau; 12. Debôd; 13. Korty; and, 14. Tafa. The small temple at Ybsambul has a head bearing a temple for the capital of its columns, like those at Denderah, but with a lock of hair hanging down on each side. The statues before the great temple, which is supposed to have been dedicated to Osiris, are of remarkably fine forms. In a small temple at Kalabshé there are some good historical sculptures of a victory obtained over the southern countries beyond Meroë. But the sculptures at Dakké Mr Burckhardt thinks superior to any others of the Egyptian school, and such as might have been considered as fit ornaments for a Grecian building. In a small temple at Samné there is still an image with the attributes of Osiris, and there are figures of a Paamyles on the walls.

Mr Burckhardt has given several Greek inscriptions, many of which had been copied by Captain Light a little differently. One of these begins with the words "This is the homage of *Caius* Cassius Celer;" not *Vulsilius*, as it had been read from Captain Light's manuscript. At Maharraka, the writer of one inscription has very benevolently included the reader in his petition for a blessing from "Isis, the goddess with ten thousand names, and from the sun Serapis." At Kardassy, an inscription dated under the Philips, the successors of the Emperor Gordian, records the munificence of Psentuaxis, who gave to the temple "twenty pieces of gold in his first priesthood, and thirty in his second." In fact, there is scarcely any trace of the old Egyptian language to be found in any existing monument, employed upon any other occasion than for the most unimportant memorials of the most insignificant personages.

---

[1] *Quarterly Review*, No. 36, 37, 38.

Several years ago, an article appeared in one of the French journals, announcing the discovery of a ruined city situated a few leagues from the Red Sea, by a young French traveller, M. Cailliaud, nearly in the latitude of Assouan, and called by the Arabs Sekelle. It has still many temples, palaces, and private houses standing, so that it may in some respects be compared to Pompeii. The architecture is Grecian, with some Egyptian ornaments; and several inscriptions prove that it was built by the Ptolemies, one of the temples having evidently been dedicated to Berenice. The situation agrees sufficiently well with that of the ancient city Berenice; but the city may easily have been at some little distance from a harbour bearing the same name; and no other town of any magnitude seems to have existed in the neighbourhood. It was through Berenice, according to Pliny, that the principal trade of the Romans with India was conducted, by means of caravans which reached the Nile at Coptos, not far from the point at which the present shorter route by Cosseir meets the river.

Whilst so much had been done abroad for the recovery of the lost treasures of Egypt, it appears that no less labour had been silently employed in pursuit of the investigation at home; and, partly with a view to perpetuate the continuance of these efforts, an association was formed in London, of which the first and immediate object was merely to insure the preservation, and to facilitate the study, of all that remains of Egyptian literature, by making a collection of drawings of all the hieroglyphical inscriptions in existence, and printing them lithographically, in a form most convenient for reference and examination, under the title of *Hieroglyphics, collected by the Egyptian Society*. The plates do credit to the manipulation of Mr Ackermann's press, as well as to the extreme neatness and accuracy of the draughtsman who was employed on them. They can scarcely be said to have been published, as they were only distributed amongst a limited number of subscribers; but as they were presented to several public libraries in different parts of Europe, they may be consulted by the general reader without difficulty.

In the midst of all the zeal and activity displayed by our countrymen who had travelled or who were resident in Egypt, it is much to be regretted that their attention had not been turned to an object paramount to all the rest in its importance for the substantial advancement of our acquaintance with the ancient history and literature of the country; that is, the recovery of the lost fragments or of some of the duplicates of the trilingual, or rather trigrammatic stone of Rosetta; a monument which has enabled us to obtain a general idea of the nature and subject of any given hieroglyphical inscription, by pursuing the investigations carried to an unexpected extent by the discoverer Dr Young, whose interpretation was communicated to the Antiquarian Society by Mr Rouse Boughton, together with copies of some fragments of manuscripts which this gentleman had brought from Egypt.[1] M. de Sacy, and more especially Mr Akerblad, had made some progress in identifying the sense of the several parts of the second or enchorial inscription of the stone; but they had scarcely at all considered the sacred characters; and it was left for British industry to convert to permanent profit a monument which had before been a useless though a glorious trophy of British valour.

It must be recollected that every analysis of an unknown object of this nature must unavoidably proceed more or less by the imperfect argumentation sometimes very properly called a circle, but which, in such instances, may be more aptly compared to a spiral, or to an algebraical approximation; since, by assuming certain incorrect suppositions, not too remote from the truth, we may render them, by means of a continual repetition of the calculation, more and more accurate, until at length the error is rendered wholly inconsiderable; and in this manner we often satisfy the conditions of a problem which it would be impracticable to solve by a more direct method. A process thus tedious and laborious, however, loses the greater part of its interest when the solution is obtained; and it is no longer necessary to explain in detail every step through which it has passed. The deciphering of the Rosetta stone is fortunately in a great measure independent of any hypothesis of this kind extraneous to itself; and the Greek text affords at once the first approximation for beginning the process. But, in order to extend the inquiry to other objects, a variety of authorities must be compared and appreciated. We must select from the Greek authors an abstract of the religious superstitions and of the civil ordinances of the Egyptians; and it will be necessary, in making this selection, to have some regard to the results which have been obtained from an examination of the principal hieroglyphical monuments still extant, in order that we may avoid the confusion which would be the necessary consequence of adopting indiscriminately the whole mass of contradictory matter, which various mythological authors have collected or invented upon the subject; and considering how absurdly and monstrously complicated the Egyptian superstitions really were, it becomes absolutely essential to separate that which is most fully established, or most generally admitted, from the accidental or local varieties which may have been exaggerated by different authors into established usages of the whole nation, and still more from those which have been the fanciful productions of their own inventive faculties. Unfortunately, by far the greater number of the existing monuments of Egypt are of a mythological nature; so that their Pantheon, or rather Pantherion, acquires an interest altogether foreign to its real character, on account of the utility of a general knowledge of the subject in developing the nature of the language employed. The accounts which have been preserved of the customs and civil ordinances of the country are still more discordant than those which relate to their deities, but they may yet in some instances be illustrated from monuments which remain in existence. Respecting the early history and chronology of Egypt, we can do little more than appreciate the various degrees of plausibility of the different fables that have been related, and the comparative credulity of the authors who have appeared to believe in them; for hitherto no hieroglyphical records have been discovered, which can afford us much assistance in this department of the investigation; though it is by no means impossible that a continued series of the sovereigns of Egypt, from the earliest times, may have been chronicled in more than one of the innumerable multitude of inscriptions hitherto uncopied and unexamined. See the article HIEROGLYPHICS.

---

[1] *Archæologia*, vol. xviii. p. 61. *Museum Criticum*, No. vi. and vii.

EGYPTIANS, or Gypsies. See Gypsies.

EHINGEN, a bailiwick of the kingdom of Wirtemberg, in the circle of the Danube. It extends over 143 square miles, comprehending two cities, two towns, and sixty-two smaller places, with 21,157 inhabitants. The capital is the city of the same name, situated on the Danube. It contains 500 houses, and 2840 inhabitants, who spin cotton yarn by means of machinery, and prepare the dyes for Turkey red. Long. 9. 51. 34. E. Lat. 48. 29. 36. N.

EHNINGEN, a city of the kingdom of Wirtemberg, in the circle of the Black Forest, where the greatest markets are held of any in the kingdom. It contains 4434 inhabitants, who make ribbons, lace, handkerchiefs, and other goods.

EHUD, the son of Gera, a Benjamite, a left-handed man, who delivered Israel from the oppression of Eglon, king of Moab, under whom they served for eighteen years. This will be found recorded in the third chapter of Judges.

EIA, or Ey, in our old writers, is used to indicate an island. Hence the names of places ending in *ey* denote that they are islands. Thus, Ramsey, the isle of rams; Shepey, the isle of sheep; and so of others.

Eia is also sometimes used for water; and hence the names of places near waters or lakes sometimes terminate in *ey*.

EIBENSTOCK, a city of the kingdom of Saxony, in the circle of Erzgeberg, and bailiwick of Krottendorf. It stands on the river Mulde, in a mining district, 1896 feet above the level of the sea, and contains 3440 inhabitants, employed chiefly in mining and preparing the metals; but the females make a large quantity of thread lace.

EICETÆ, called also Heicetæ and Hicetæ, were heretics of the seventh century, who made profession of the monastic life. From the passage in Exodus where Moses and the children of Israel are said to have sung a song in praise of the Lord, after they had safely passed the Red Sea, the Eicetæ concluded that, in order to praise God aright, the introduction of singing and dancing was necessary; and as Mary the prophetess, sister of Moses and Aaron, beat a drum on the same occasion, an example which was followed by all the other women to express their joy, the Eicetæ, in order the better to imitate them, enticed females to make profession of the monastic life, and assist in their mirth.

EICHSTEDT, a bailiwick of the circle of the Regen, in the kingdom of Bavaria. It was formerly under the dominion of the Duke of Leuchtenberg, but has been mediatised. It extends over 470 square miles, and comprehends four cities, nine market-towns, a hundred and eleven villages, and seventy hamlets, with 45,256 inhabitants. It is a well-watered and well-cultivated district. The mountains contain iron, slates, and marble. It was given by the late king to his son-in-law Eugene Beauharnois, and was said to have yielded L.25,000 yearly. The capital is a city of the same name, which stands in a narrow valley on the river Altmühl. It is surrounded with walls, and has a castle the residence of the prince, a cathedral, a gymnasium, an orphan house, six churches, 900 houses, and 5596 inhabitants, some of whom are employed in manufacturing fine thin cloths and some other articles. Long. 11. 6. 5. E. Lat. 48. 53. 30. N.

EIDER Duck. See Ornithology.

Eider *Down*, the down of the eider duck. The eider duck plucks off the down from its breast for the purpose of making its nest, which it continues to renew as often as deprived of it, until its breast becomes quite bare.

In commerce this down is sold in balls about the size of a man's fist, and weighing from three to four pounds. It is so remarkably fine and elastic, that if one of these balls be opened and cautiously held over a fire to expand, it will fill a quilt about five feet square. Supplies of it are received chiefly from Norway, Iceland, and the Faroe Islands, where the birds abound. There are two kinds of it, sea-weed down and grass down. The former is the heaviest, but not so easily cleaned as the other.

EILAU-PRUSSIAN, or Eylau-Preussischen, a town of the province of East Prussia, and government of Königsberg. It contains a hundred and ninety-eight houses, and 1634 inhabitants. It is remarkable for the great battle fought there on the 7th and 8th February 1807, between the French and the united Russian and Prussian armies.

EILENBURG, a city of the Prussian province of Saxony, in the circle of Deletzsch. It is situated on an island formed by the Mulda, is surrounded with walls, and contains 573 houses, and, with the military, 4545 inhabitants. There are establishments for the printing of calico, and for other manufactures.

EIMBECK, or Einbeck, a city of the province of Grubenhagen, in the kingdom of Hanover, at the foot of the Hartz Mountains. It is walled, and contains 784 houses, with 4995 inhabitants employed in various trades.

EINDHOVEN, a city of the province of North Brabant, in the Netherlands. It stands at the junction of the rivers Gender and Dommel, and contains 390 houses, and 2810 inhabitants. Long. 5. 23. 20. E. Lat. 51. 25. 26. N. It is the capital of a circle of the same name, divided into seven cantons, which contain 85,066 inhabitants.

EINSHEIM, a bailiwick in the circle of the Neckar, in the duchy of Baden, in Germany, comprehending one city, sixteen villages, and five hamlets, with 14,370 inhabitants; the capital of which, of the same name, stands on the river Elsenz, and has 186 houses, with 2358 inhabitants.

EISENACH, a principality, forming a considerable part of the grand duchy of Saxe-Weimar, in Germany. It extends over 456 square miles, comprehending seven cities, six market towns, 228 villages, 12,920 houses, and 65,549 inhabitants. It is a scattered principality, many portions of which are surrounded by the territory of other sovereigns. The city of Eisenach, the capital of the principality, is situated on the river Nesse, at the foot of a range of lofty hills, from the summit of which a fine view is obtained over a great part of Saxony. It contains 1490 houses and 8258 inhabitants. It is a place of active industry in a great variety of manufactures, particularly those of cotton and woollen. Near to it is the castle of Wartburg, situated on a lofty rock, and celebrated as the place of confinement of Martin Luther. Being on the high road between Frankfort and Leipsic, it has a great transit trade. It is in longitude 10. 13. 51. east, and latitude 50. 57. 7. north. Eisenach is also the capital of a bailiwick of its own name, which comprehends one city, one market-town, nineteen villages, and twelve hamlets, with 17,325 inhabitants.

EISENBURG, a city of the principality of Altenburg, in the grand duchy of Saxe-Gotha, in Germany. It is situated on a remarkable elevation, is surrounded with walls, and contains a ducal palace, three churches, 546 houses, and 4243 inhabitants, who make cotton goods, ribbons, furniture, porcelain, leather, and other articles. It is the capital of a bailiwick of the same name, with 13,000 inhabitants.

EISLEBEN, a city of the province of Prussian Saxony, the capital of the circle of Mansfeld. It is divided into the old and the new city, is surrounded with walls, and has several establishments for education, four churches, 957 houses, and 7100 inhabitants. It is celebrated as the birth-place of Martin Luther, the house where he was born being now used as a charity school. It is a place of considerable trade and manufacturing industry. Long. 11. 26. 5. E. Lat. 51. 53. 5. N.

EJECTMENT, in *English Law*, a writ or action which lies in favour of the lessee for years, on his being ejected or put out of his land before the expiration of his term, either by the lessor or a stranger. It may also be brought by the lessor against the lessee, for rent in arrears, or holding over his term, and the like.

EKATERINOGRAD, a town and fortress of Asiatic Russia, in the government of Caucasus, on the river Mulka or Balk, which a little lower falls into the Terek. It is the strongest place on the Caucasian line of posts, having been founded in the year 1776; and it remained the capital of the province of Caucasus, until it was constituted a government in 1785. It is twenty-four miles north-west of Mozdok.

EKRON, a city and government of the Philistines. It fell by lot to the tribe of Judah, in the first division made by Joshua, but it was afterwards given to the tribe of Dan. It was situated very near the Mediterranean, between Ashdod and Jamnia. Ekron was a powerful city, and it does not appear from history that the Jews were ever peaceable possessors of it. The idol Beelzebub was principally adored at Ekron.

ELÆOTHESIUM, in *Antiquity*, the anointing room, or place where those who were to wrestle or had bathed anointed themselves. See GYMNASIUM.

ELAM, in *Ancient Geography*, a country frequently mentioned in Scripture, and situated to the south-east of Shinar. In the time of Daniel (viii. 2) Susiana seems to have been part of that country; and before the captivity it does not appear that the Jews recognised Persia by any other name. Elymæ and Elymais are frequently mentioned by the ancients. Ptolemy, although he makes Elymais a province of Media, yet places the Elymæ in Susiana, and near to the sea; but Stephanus supposes it to have been part of Assyria, and Pliny and Josephus more properly part of Persia, whose inhabitants, we are informed by the latter, were descendants of the Elamites. The best commentators agree that the Elamites were sprung from Elam the son of Shem. It is likewise allowed that the most ancient amongst the inspired writers constantly allude to Persia when they speak of Elam and the kingdom of Elam.

ELAPHEBOLIA, in Grecian antiquity, a festival observed in honour of Diana the huntress. In the celebration of this mystery a cake was made in the form of a deer (ελαφος), and offered to the goddess. It owed its institution to a notable circumstance. When the Phocians had been severely beaten by the Thessalians, they resolved, by the persuasion of one Deiphantus, to raise a pile of combustible materials, and to burn their wives, children, and effects, rather than submit to the enemy. This flaming resolution was unanimously approved of by the women, who decreed Deiphantus a crown for his magnanimity. But when every thing was prepared, and just before they had fired the pile, they engaged their enemies, whom they totally routed, and thus obtained a complete victory. In commemoration of this unexpected success, the festival was instituted, and observed with the greatest solemnity.

ELAPHEBOLIUM, in Grecian antiquity, the ninth month of the Athenian year, answering to the latter part of February and the beginning of March. It consisted of thirty days, and took its name from the festival Elaphebolia, observed in this month in honour of Diana the huntress, as mentioned above.

ELASTIC, in *Natural Philosophy*, an appellation given to all bodies endowed with the property of elasticity.

ELASTICITY, or ELASTIC FORCE, that property which bodies possess of restoring themselves to their former figure, after any force which has disturbed it is withdrawn. Elasticity is generally accounted for by the great law of attraction. Thus, when a hard body is struck or bent, so that the component parts are moved a little from each other, but not so far as to overcome the power of the attractive force by which they cohere, they necessarily, on the cessation of that external force, return to their former state. All hard bodies are elastic, as steel, glass, and ivory, and many soft ones, as caoutchouc, silk thread, &c. The reniform bodies are all perfectly elastic. Liquids are also perfectly elastic, but to a small extent.

ELATEA, the largest and most important city of Phocis, situated on the declivity of a hill above the fertile plains of the river Cephissus. Behind it to the north rose a mountain ridge, which, issuing from Doris, stretched away to the south-east, and at its extremity was called by the name of Cnemis. Here dwelt the Locri Epicnemidii. An enemy who wished to penetrate from Thermopylæ by the most direct road into Greece required first to secure the mountain passes round Elatea, and to get possession of the city itself. Then the whole of Phocis and Bœotia lay open before him. Hence the alarm and consternation produced at Athens on the news reaching it of Elatea having fallen into the hands of Philip. (Demosth. *Orat. de Cor.* p. 284; Strab. ix. 424; Diodor. xvi. 84.) It was burnt to the ground by the Persians, and destroyed at the conclusion of the sacred war by order of the Amphictyonic council. Being afterwards rebuilt, it made a successful stand against the arms of Cassander, and was at last taken by the Romans from Philip, son of Demetrius. Its ruins are found on a site still called *Elephta*.

ELATERIUM, Ελατηριον, in *Pharmacy*, a violently purgative medicine, prepared from the wild cucumber.

ELATH, or ELOTH, a port of Idumæa, situated upon the Red Sea, which David in his conquest of Edom took, and established there an extensive trade. His son, we are informed, built ships in Elath, whence they were dispatched to Ophir for gold. It continued in the possession of the Israelites till the time of Joram, when the Edomites recovered it; but it was wrested from them by Azariah, who left it to his son. It was afterwards taken from Ahaz by the Syrians, who held it a long time; and it passed at length into the hands of the all-subduing Romans.

ELBA, an island of the Mediterranean, separated by a narrow channel from the western coast of Italy. It is situated in long. 10. 9. 24. E. and lat. 42. 49. 6. N., and is about seventy English miles in circuit; but the coast is very winding and irregular.

Elba is supposed to have been first peopled by a colony of Etruscans; but it was afterwards occupied by a body of the Greeks who founded Marseilles. It subsequently fell under the dominion of Carthage, and was taken by the Romans during the first Punic war. In the second, Elba supplied iron for naval and military purposes, and was considered as one of the states which had saved the republic. In the contest between Sylla and Marius, the adherents of the latter fled thither for refuge, and Elba became thus involved in prescription and devastation, from the effects of which it never recovered under the Roman dominion. In modern times it became attached to the commercial republic of Pisa, under the auspices of which it rose to a comparatively flourishing state. On the annexation of Pisa to Milan, Elba, with Pianosa, Monte Cristo, Piombino, and other territories, was formed into a little principality, which continued for about two centuries in the hands of Gherardo d'Apiano and his successors; though it was repeatedly occupied as a military station by Charles V. and his ally, the grand duke of Tuscany. Being thus involved in the wars of that monarch with the Porte and the Barbary states, Elba became exposed to the incursions of the Turkish corsairs. It was laid waste with fire and sword, once by Barbarossa, and twice by Dragut, and it has never fully recovered from these ravages. Under Philip III. it fell into the possession of Spain, and that prince ordered the construction of Porto Longo, which proved a barrier against the incursions of the corsairs. Several transferences afterwards took place, the result of which was, that after 1735 the king of Naples had possession of Porto Longo, and the grand duke of Tuscany of Porto Ferrajo. Elba continued in this state till the French revolution, when it first became part of the kingdom of Etruria, and was then annexed to France. It afterwards attracted a remarkable degree of attention by becoming the temporary residence of Napoleon Bonaparte. Upon his second downfall, Elba was ceded to the grand duke of Tuscany.

The island of Elba is entirely filled with mountains, which are formed into three distinct clusters, separated by a valley, which widens as it approaches the sea. The highest are those situated on the western part of the island, the pinnacle of which, called Monte Capanna, rises upwards of 3000 feet above the level of the sea. The greater part of these hills present an arid, rugged, and often ruinous aspect; but a few are embellished with myrtles, laurels, wild olives, and other verdant shrubs. The western part is almost entirely composed of granite, which forms also the basis of the soil in this quarter of the island. Rock crystal abounds, and is often found in large masses, but somewhat injured in its transparency, and, when combined with alum and slate, it produces numerous varieties of calcedony, particularly that called *cachalong*. The eastern mountains are composed of serpentine and schistus, and abound with aluminous mixtures; but they are chiefly distinguished by the iron which they contain.

Except husbandry, which is wholly that of the spade or the hoe, the chief employment of the inhabitants consists in mining, and iron is the chief article of exchange.

The population in 1778 was estimated at 8000, but it has since risen to 12,000 souls. The Elbese are a race differing in many respects from that which inhabits the continent of Italy. They are well made and robust, and often attain a great age without experiencing ailment or infirmity. They are brave, active, hardy, laborious, and at the same time kind-hearted and hospitable. They are, however, very irritable, and impatient of contradiction. They are almost universally ignorant and credulous, yet have a certain liveliness of imagination, which renders them fond of extravagant and romantic tales. The females are not in general handsome, but to this there are some exceptions; they are generally virtuous, however, and make good wives and mothers.

The principal town is Porto Ferrajo, which contains a population of 3000 souls. The houses are small and inconvenient. Porto Longo is a well-fortified town, with an agreeable and picturesque neighbourhood, and contains 1500 inhabitants. Rio is poor, and is only supported by the great iron mine which is situated in its neighbourhood; its population amounts to about 1800 souls. Other villages and districts are Capo Liveri, Campo, and Marciano.

(*Voyage to the Island of Elba*, by Arsenne Thiebaut de Berneaud; translated by W. Jordan, 8vo, 1814. *Tour through the Island of Elba*, by Sir Richard Colt Hoare, Bart. 4to, 1814.)

ELBE (the *Albis* of the ancients), a large river of Europe, in Germany, which rises in the *Riesen Gebirge*, or Giant's Mountains, between Silesia and Bohemia, and is known at its source by the Sclavonic name of the *Labbe*. Its principal sources are the White Fountain, at the base of the *Schnee-Kuppe*, and the eleven fountains of the Elbe in the Navarian meadow. To the number of streams which descend into Bohemia from the neighbouring mountains it owes its early increase. After its junction with the river Eger, it becomes navigable, and, entering Saxony, passes successively Dresden, Meissen, Torgau, and Wittenberg. In its course, which is northerly, it receives two other rivers, the Muldau and the Saale; and running through the territory of Magdeburg and the duchies of Mecklenburg and Launburg, it discharges itself at last into the German Ocean, about seventy miles below Hamburg, after a course of 500 miles. The Elbe has always been an important river in a military point of view. With respect to commerce, it gives to Hamburg its command of the navigation far into the interior, although the voyage is difficult, on account of the numerous sand-banks, and the occasional violence of the wind. It communicates with the Havel by the canal of Plauen, in the territory of Magdeburg; and at Hamburg it is connected in like manner with the Trave at Lubeck; it is also joined to the Weser by a canal running between Vegesak and Stade. Besides the natural difficulties of navigating this noble stream, the circumstance of its traversing so many different kingdoms and petty states has given rise to another, namely, the endless tolls imposed by the princes of the various sovereignties through which it passes. The congress of Vienna intended to rectify this evil; but, notwithstanding the regulations introduced, the navigation of the German rivers cannot yet be called free.

ELBERFELD, a city of the Prussian province Clewe-Juliers, of the government of Dusseldorf, and the capital of a circle of the same name. It stands on the river Wipper, which falls into the Rhine a few miles from the city. It is a place the most celebrated for its activity and progress of any in the Prussian dominions. In 1817 the houses were 2400, and the inhabitants 15,681, and in 1830 the latter had increased to 25,000. It has more than 1000 looms at work in silk goods, many mills for spinning cotton, besides machines for weaving cottons, and most of the other inventions for facilitating manufacturing operations which are known in England. The value of the goods annually produced at and near to the city is said to amount to L.1,500,000 sterling. It is the chief seat of the Rhenish company, who export the various goods of Germany to the West Indies and all parts of North and South America.

ELBEUF, a city of the department of the Lower Seine, in France, on the left bank of that river, containing 919 houses, and 6351 inhabitants, among whom are many manufacturers of the finest cloth, and of flannels, carpets, and hosiery. Long. 0. 53. E. Lat. 49. 20. N.

ELBING, a city in the province of West Prussia, and government of Dantzic, and the capital of a circle of the same name. It is situated on the river Eblach, which divides the suburb of Grubenhagen, and the part where the corn magazines are built, from the town. About five miles below the city that river joins the Nogat, which is navigable for large vessels. Elbing contains six churches, five hospitals, and several other public buildings, with 2029 houses and 18,570 inhabitants. It is, next to Dantzic, the greatest corn market of Europe, and a stock of wheat is generally kept there amounting to from forty to eighty thousand quarters. A great portion of the productions of Poland is exported from this city. These, besides corn, consist of potash, pearl ash, linen, wood, tallow, and wax; and that country receives a part of its supply of manufactured and coloured goods, of wine, of iron, of salt, and other articles, through the same channel. The city possesses some manufactories, such as refineries for sugar, soap-boiling, snuff-mills, breweries, and tanneries; and many ships are built and equipped. Long. 19. 16. 5. E. Lat. 54. 7. 54. N.

ELBOW, the outer angle made by the flexure or bend of the arm. That eminence whereon the arm rests, called by us *elbow*, is by the Latins called *cubitus*, and by the Greeks αγκων, and by others ολεκρανον.

Elbow is also used by architects, masons, and others, for an obtuse angle of a wall, building, or road, which diverts it from its right line.

ELCESAITES, in *Ecclesiastical History*, were ancient heretics, who made their appearance in the reign of the Emperor Trajan, and took their name from their leader Elcesai. The Elcesaites observed a mean between the Jews, Christians, and Pagans. They worshipped but one God, observed the Jewish sabbath, and practised circumcision and the other ceremonies of the law. They rejected the Pentateuch and the prophets; nor had they any more respect for the writings of the apostles, particularly those of St Paul.

ELCHE, a town of Spain, in the province of Valencia. It is situated on a small river that runs into the Guadarma. It is celebrated for the beauty of its palm woods, and for the exquisite marbles raised in the quarries in its vicinity. It is situated in latitude 38. 29. and contains 2600 houses and 17,405 inhabitants, three monasteries, an hospital, poor-house, one Latin and three other schools. Manufactories of esparto, tanning, and soap-making, are carried on at this place.

ELDERS, or Seniors, in Jewish history, were persons the most considerable for age, experience, and wisdom. Of this sort were the seventy men whom Moses associated to himself in the government of his people; such as were those who afterwards held the first rank in the synagogue as presidents.

In the first assemblies of the primitive Christians, those who held the principal place were called *elders*. The word *presbyter*, so often used in the New Testament, is of the same signification; and hence the first council of Christians were called *presbyteria*, or *councils of elders*.

Elders is also a denomination still retained in the Presbyterian discipline. The elders are officers, who, in conjunction with the pastors or ministers, and deacons, compose the consistories or kirk-sessions, meeting to consider, inspect, and regulate matters of religion and discipline. They are chosen from among the people, and are received publicly with some degree of ceremony. In Scotland, the number for each parish or congregation is indefinite, varying according to circumstances.

ELEA, or Elis, in *Ancient Geography*, a district of Peloponnesus, situated between Achaia and Messenia, and stretching from Arcadia to the west or Ionian Sea. It is so called from Elis, a cognominal town.

ELEATIC Philosophy, amongst the ancients, a name given to that of the Stoics, because it was taught at Ελεα, in Latin *Velia*, a town of the Lucani.

The founder of this philosophy, or of the Eleatic sect, is supposed to have been Xenophanes, who lived about the fifty-sixth Olympiad, or between five and six hundred years before Christ. This sect was divided into two parties, which may be denominated *metaphysical* and *physical*, the one rejecting and the other approving the appeal to fact and experiment. Of the former persuasion were Xenophanes, Parmenides, Melissus, and Zeno of Elea. They are supposed to have maintained principles not very unlike those of Spinoza: they held the eternity and immutability of the world; that whatever existed was only one being; that there was neither generation nor corruption; that this one being was immoveable and immutable, and was the true God; and that whatever changes seemed to happen in the universe were to be looked upon as mere appearances and illusions of sense. However, it is supposed by some that Xenophanes and his followers, speaking metaphysically, understood by the universe, or the one being, not the material world, but the great originating principle of all things, or the true God, whom they expressly affirm to be incorporeal. Thus Simplicius represents them as merely metaphysical writers, who distinguished between things natural and supernatural, and who supposed the former to be compounded of different principles. Accordingly, Xenophanes maintained that the earth consisted of air and fire; that all things were produced from the earth; that the sun and stars sprung from clouds; and that there were four elements. Parmenides also distinguished between the doctrine concerning metaphysical objects, called *truth*, and that concerning physical or corporeal things, called *opinion*. With respect to the former, there was one immoveable principle, but in the latter, two that were moveable, namely, fire and earth, or heat and cold; and in these particulars Zeno agreed with him. The other branch of the Eleatic sect were the atomic philosophers, who formed their system from observing the phenomena of nature; of these the most considerable were Leucippus, Democritus, and Protagoras.

ELECT or *Chosen* (from *eligo*, I choose), in the Scriptures, is applied to the primitive Christians; in which sense the elect are those chosen and admitted to the favour and blessing of Christianity.

Elect, in some systems of theology, is a term appropriated to the saints, or the predestinated; in which sense the elect are those persons who are said to be predestinated to glory as the end, and to sanctification as the means.

Elect is likewise applied to archbishops, bishops, and other officers, who are chosen, but not consecrated, or actually invested with their office or jurisdiction.

The emperor is said to be elect before he is inaugurated and crowned; and a lord mayor is elect before his predecessor's mayoralty is expired, or the sword is put in his hands.

ELECTION, the choice that is made of any person or thing by which he or it is preferred to any other. There seems this difference, however, between choice and election, that election has usually a regard to a company or community which makes the choice; whereas choice is seldom used but when a single person makes it.

Election, in British polity, is the people's choice of their representatives in parliament. (See Parliament.)

Election is also the state of a person who is left to his own free will, to take or do just what he pleases.

Election, in *Theology*, signifies the choice which God, of his good pleasure, makes of angels or men, as the objects of mercy and grace.

The election of the Jews was the choice God made of that people to be more immediately attached to his worship and service, and for the Messiah to be born of them. And thus particular nations were elected to the participation of the outward blessings of Christianity.

Election also, in the language of some divines, signifies a predestination to grace and glory, and sometimes to glory only. And it has been enjoined as an article of faith, that predestination to grace is gratuitous; *gratia, quia gratis data*. But the divines are much divided as to the point, whether election to glory be gratuitous, or whether it supposes obedience and good works; that is, whether it be before or after the provision of our obedience.

ELECTIVE, something that is done, or passes, by election.

Elective *Attraction*. See Chemistry.

ELECTOR, a person who has a right to elect or choose another to an office, honour, and the like.

ELECTORATE, a term used indiscriminately to signify the dignity of, or the territories belonging to, any of the electors of Germany; such as Baden, Saxony, &c. See Germany.

ELECTRICITY.

In duc- n.

Electricity, from the Greek word ηλεκτρον,[1] *electron*, *amber*, is the name given to a modern science which treats of the phenomena and effects produced by the friction of amber, and other bodies which possess analogous properties.

The science of Electricity, in its most general acceptation, may be divided into four different branches, viz.

I. *Ordinary Electricity*, or that which is developed by friction.

II. *Magneto-Electricity*, or that which is developed by magnets.

III. *Thermo-Electricity*, or that which is developed by heat; and

IV. *Voltaic Electricity*, or that which is produced by chemical action.

Under these four articles we shall be able, not only to give a perspicuous and condensed view of those splendid discoveries which have illustrated the present age, but to render our account of them much more complete than if we had treated the subject under the titles of *Electro-magnetism* and *Galvanism*, which occur so early in our alphabetical arrangement.

In giving a succinct and popular view of the science of *Electricity* in the ordinary acceptation of the word, the subject naturally divides itself into two parts: 1*st*, On the phenomena and laws of electricity; and, 2*dly*, on the instruments and apparatus used in electrical experiments. Before we proceed, however, to these topics, we shall give a brief history of the origin and progress of the science.

HISTORY OF ELECTRICITY.

Tes, B. 600.

The name of the philosopher who first observed that amber when rubbed possesses the property of attracting and repelling light bodies has not been handed down to our times. Thales of Miletus is said to have described this remarkable property, and both Theophrastus (B. C. 321) and Pliny (A. D. 70) mention the power of amber to attract *straws* and *dry leaves*. The same authors speak of the *lapis lyncurius*, which is supposed to be a mineral called *tourmaline*, as possessing the same property.

A hal ricity.

The electricity of the torpedo was also known to the ancients. Pliny informs us, that when touched by a spear it paralyses the muscles and arrests the feet, however swift; and Aristotle adds that it possesses the power of benumbing men, as well as the fishes which serve for its prey. The influence of electricity on the human body, and the electricity of the human body itself, were also known in ancient times. Anthero, a freedman of Tiberius, was cured of the gout by the shocks of the torpedo; and Wolimer, the king of the Goths, was able to emit sparks from his own body.

A 415.

Eustathius, who records this fact, also states that a certain philosopher, while dressing and undressing, emitted occasionally sudden crackling sparks, while at other times flames blazed from him without burning his clothes.

Such are the scanty gleanings of electrical knowledge which we derive from the ancient philosophy; and though several writers of the middle ages have made occasional references to these facts, and even attempted to speculate upon them, yet they added nothing to the science, and left an open field for the researches of modern philosophers.

History.

Gilbert, A. D. 1600.

Our countryman Dr Gilbert of Colchester may therefore be considered as the founder of the science of electricity, as he appears to have been the first philosopher who carefully repeated the observations of the ancients, and applied to them the principles of philosophical investigation. In order to determine if other bodies possessed the same property as amber, he balanced a light metallic needle on a pivot, and observed whether or not it was affected by causing the excited or rubbed body to approach to it. In this way he discovered that the following bodies possess the property of attracting light substances: Amber, gugates or jet, diamond, sapphire, carbuncle, rock crystal, opal, amethyst, vincentina or Bristol stone, beryl, crystal, paste for false gems, glass of antimony, flags, belemnites, sulphur, gum-mastic, sealing-wax of lac, hard resin, arsenic, sal gem, mica, and alum.

These various bodies attracted, with different degrees of force, not only straws and light films, but likewise metals, stones, earths, wood, leaves, thick smoke, and all solid and fluid bodies. Among the substances which are not excited by friction, Gilbert enumerated emerald, agate, carnelian, pearls, jasper, chalcedony, alabaster, porphyry, coral, marble, Lydian stone, flints, hæmatites, mugris (*emery* or *corundum*), bones, ivory, hard woods, such as cedar, ebony, juniper, and cypress, metals and natural magnets.

Having thus determined the bodies which were capable, as well as those which were incapable, of electrical excitation, Dr Gilbert was desirous of ascertaining the circumstances which were most favourable to the production of electricity. When the wind blew from the north and east, and when the air was dry, the body was excited in about ten minutes after the friction commenced; but when the wind was in the south, and the air moist, the attractive power of the body was greatly diminished, and in some cases it could not be excited at all.

Boyle, A. D. 1675.

The celebrated Mr Boyle added many new facts to the science of electricity, and he has given a full account of them in his *Experiments on the Origin of Electricity*. By means of a suspended needle, he discovered that amber retained its attractive virtue after the friction which excited it had ceased; and though smoothness of surface had been regarded as advantageous for excitation, yet he found a diamond which in its rough state exceeded all the polished ones and all the electrics which he had tried, having been able to move a needle three minutes after he had ceased to rub it. He found also that heat and *tersion* (or the cleaning or wiping of any body) increased its susceptibility of excitation; and that if the attracted body were fixed, and the attracting body moveable, their mutual approach would still take place. To Dr Gilbert's list of electrics Mr Boyle added the resinous cake which remained after evaporating one fourth part of good oil of turpentine; the dry mass which remains after distilling a mixture of petroleum and strong spirit of nitre, glass of antimony, glass of lead, caput mortuum of amber, white sapphire, white amethyst, diaphanous ore of lead, carnelian, and a green stone supposed to be a sapphire.

Otto Guericke, born 1602, died 1686.

To these discoveries of Mr Boyle, his illustrious contemporary Otto Guericke added the highly important one of *electric light*. Having cast a globe of sulphur in a glass sphere, the glass was broken, and the sulphur ball mounted upon a revolving axis, and excited by the friction of the hand. By this means he discovered that light and sound accompanied strong electrical excitation, and he compares the light to that which is exhibited by breaking lump sugar in the dark. With this powerful apparatus Guericke verified on a greater scale the results obtained by his predecessors, and obtained several new ones of very considerable importance. He found that a light body, when once attracted by an excited electric, was repelled by it, and was incapable of a second attraction until it had been touched by some other body; and that light bodies suspended within the sphere of influence of an excited electric, possessed the same properties as if they had been excited.

---

[1] According to Salmasius, the word *karabe*, the Arabian word for *amber*, signifies the power of attracting straws. May not ηλεκτρον (ηλεκτριανος λιθος) come from ελκω, to *draw* or *attract*, and θριξ-τριχος, a *hair* or *filament*, or θριον, a leaf?

Newton, born 1642, died 1727.

To our illustrious countryman Sir Isaac Newton the science of electricity owes some important observations. He seems to have been the first person who constructed an electrical machine of glass. "A globe of glass," says he, "about eight or ten inches in diameter, being put into a frame where it may be swiftly turned round its axis, will in turning shine when it rubs against the palm of one's hand applied to it; and if at the same time a piece of white paper or a white cloth, or the end of one's finger, be held at the distance of about a quarter of an inch or half an inch from that part of the glass when it is most in motion, the electric vapour which is excited by the friction of the glass against the hand will, by dashing against the white paper, cloth, or finger, be put into such an agitation as to emit light, and make the white paper, cloth, or finger, appear lurid like a glow-worm, and in rushing out of the glass will sometimes push against the finger so as to be felt. And the same things have been found by rubbing a long and large cylinder of glass and amber with a paper held in one's hand, and continuing the friction till the glass grew warm."[1] We owe also to Sir Isaac a beautiful experiment on the excitation of electricity on the side of a disc of glass opposite to the side which was rubbed. Having fixed a round disc of glass at the distance of one third of an inch from one end of a brass hoop or ring, and one eighth of an inch from another, he placed small pieces of thin paper within the brass ring and upon a table, so that the lower surface of the glass was one eighth of an inch distant from the table. He then rubbed the upper surface of the glass, and he observed the pieces of paper "leap from one part of the glass to the other, and twirl about in the air." Upon sliding his finger upon the upper side of the glass, he also observed that the pieces of paper, as they hung under the glass, inclined this way or that according as he moved his finger. The Royal Society had ordered this experiment to be tried at their meeting of the 16th December 1675; and, in order to ensure its success, had obtained the above account of it from Sir Isaac. The experiment however failed, and the secretary requested the loan of Sir Isaac's apparatus, and inquired whether or not he had secured the papers from being moved by the air which might have somewhere stolen in. In Sir Isaac's reply, dated 21st December, he recommended them to rub the glass "with stuff whose threads may rake its surface, and if that will not do, to rub it with the finger ends to and fro, and knock them as often upon the glass." By means of these directions, the society succeeded with the experiment on the 13th January 1676, when they used "a scrubbing brush of short hog's bristles, and the heft of a knife made with whalebone."[2]

Hawksbee, A. D. 1705.

Mr Francis Hawksbee, one of the most active and ingenious experimental philosophers of his age, added many new facts to the science. In 1705 he communicated to the Royal Society several curious experiments on what he calls "the mercurial phosphorus." He showed that light could be produced by passing common air through mercury placed in a well-exhausted receiver. The air rushing through the mercury, blew it up against the sides of the glass that held it, "appearing all around like a body of fire, consisting of abundance of glowing globules." The phenomenon continued till the receiver was half full of air. When the mercury was made to descend in vacuo from the top to the bottom of a receiver about twenty-one inches high, it fell in minute particles, "like a shower of fire, in a very surprising manner." In repeating this experiment with about three pounds of mercury, and making it break into a shower by dashing it against the crown of another glass vessel, *flashes resembling lightning*, of a very pale colour, and very distinguishable from the rest of the produced light, were dashed from the crown of the glass, sometimes horizontally, and at other times upwards and downwards. Mr Hawksbee likewise showed that considerable light may be produced from mercury, by giving it motion before the receiver was quite exhausted; and that even in the open air "abundance of particles of light are discoverable by shaking quicksilver in a glass."

In a subsequent series of experiments on the attraction of bodies in vacuo, he showed that light was generated by the swift attrition of amber on woollen; that a purple light was produced by the attrition of glass on woollen; and that a considerable light was developed by the attrition of glass on glass in vacuo, and in common air, or under water. During the attrition of glass on woollen, Hawksbee "observed the light to break from the agitated glass *in as strange a form as lightning*," particularly when he used some list of cloth that had been drenched in spirit of wine. In all these experiments Hawksbee was not aware that the light which he observed was that of electricity.

Like Sir Isaac Newton, Hawksbee used a glass globe capable of revolving in a wooden frame, and by its assistance he made a great number of experiments, which are not sufficiently important to be given in detail. The following experiment, however, is too interesting to be omitted. Having coated more than one half of the inside of a glass globe with sealing wax, which in some places was an eighth of an inch thick, and therefore absolutely opaque, he exhausted it and put it in motion. When his hand was applied to excite it, the form of his hand was distinctly seen in the concave surface of the wax, as if it had become transparent. The same result was obtained when pitch or common brimstone was substituted in place of sealing-wax.

We have already seen that Hawksbee observed the resemblance between the electric spark and lightning. Dr Wall went a step farther, and compared the crackling and the flash of excited amber to thunder and lightning. The crackling he found to be fully as loud as that of charcoal on fire when the finger was held at a little distance from the amber after it had been drawn gently and slightly through a piece of woollen cloth.

Mr St phen G r, 1720– 36

One of the most ardent experimentalists of the present time was Mr Stephen Gray, a fellow of the Royal Society. In his first paper, published in 1720, he showed that electricity could be excited by the friction of feathers, hair, silk, linen, woollen, paper, leather, wood, parchment, and gold-beaters' skin. Several of these bodies exhibited light in the dark, especially after they had been warmed; but all of them attracted light bodies, and sometimes at the distance of eight or ten inches.

The communication of electricity to bodies not capable

---

[1] *Optics*, query 8th.

[2] Brewster's *Life of Sir Isaac Newton*, p. 307, 308.

Dr Wall, A. D. 1708.

of excitation was the next discovery of Mr Gray. An ivory ball, and various other substances of a metallic, animal, and vegetable nature, were made to attract light bodies by connecting them with strings, wires, or pieces of wood, with one extremity of an excited glass tube; and by suspending pack-threads of different lengths with silken threads, he was able to transmit the electrical influence in any direction to distances of 50, 147, 293, and finally 765 and 886 feet.

In order to determine if the electric attraction is proportioned to the quantity of matter in bodies, Mr Gray and Mr White made two cubes of oak about six inches square, the one solid and the other hollow. When suspended by hair lines, and similarly electrified by an excited glass tube, both the cubes attracted and repelled leaf brass at the same time and to the same height. Hence Mr Gray concluded *that it was the surface of the cubes only which attracted.*

The conducting powers of fluids and of the human body were next ascertained by Mr Gray. Having blown a soap bubble with an electrified tobacco pipe, he found that the lower part of the bubble attracted small pieces of Dutch metal; and when a boy eight or nine years old, and weighing 47 lbs., was suspended upon hair lines, he found that every part of his body exercised a strong electrical action upon light bodies, and hence he concluded "that animals receive a greater quantity of electrical effluvia." When an excited tube was held above water or quicksilver placed in little ivory dishes, the fluid was attracted upwards into little conical mounds, accompanied with a snapping noise and a discharge of light from their summit. In sunshine small particles of water rose from the top of the fluid cone, and sometimes a fine stream of water like a fountain, from which there arose a fine steam or vapour. Hot water was attracted much more powerfully, and at a much greater distance, and the steam was more distinctly visible. Mercury did not rise so high as the water; but the snapping noise was louder, and continued much longer, than when water was employed.

Mr Gray now set himself to discover "whether there might not be a way found to make the property of electrical attraction more permanent in bodies." Having procured iron ladles of several sizes, he melted the substances given in the following table. They were then set by in the ladle to cool and harden, and afterwards being replaced on the fire so as to allow what was next the bottom and sides of the ladle to melt, the ladle was inverted, and the substance taken out. These bodies at first would not attract light substances till their temperature was nearly that of a hen's egg; but when cold they attracted ten times farther than at first. In order to preserve these bodies in a state of attraction, he wrapped them up in flannel or white paper or black worsted stockings, and then put them into a large fir box till they were used. The following is Mr Gray's list of the electrics thus formed:—

Names.	Weight Avoird.		Time when made.
	oz.	oz.	
Fine black rosin	2	0	Jan. 31.
Stone pitch, and black rosin	2	2	Jan. 31.
Fine rosin and bees' wax	2	1	Feb. 1.
Stone pitch	1	7	Feb. 1.
Stone sulphur	3	6	Feb. 4.
Shell lack	10	0	Feb. 10.
Fine black rosin	10	4	Feb. 10.
Bees' wax and rosin	9	0	Feb. 12.
Rosin 4, gum lac 1 part	10	0	Feb. 12.
Sulphur	18	0	Feb. 15.
Stone pitch	10	12	Feb. 16.
Black rosin	23	0	Feb. 23.
White rosin	7	12	Feb. 25.
Gum-lac	11	14	Feb. 26.
Gum-lac and black rosin	9	12	Feb. 26.
Gum-lac 4, rosin 1 part	17	8	Feb. 28.
Gum-lac, fine black rosin	28	4	March 2.
Cylinder of blue sulphur	19	4	March 20.
Large cone of ditto	30	0	March 29.
Cake of sulphur	11	4	April 29.

Mr Gray continued for thirty days to observe every one of these bodies, and at the end of that time he found that they attracted as vigorously as at the first or second day, and some of them continued to preserve their attraction for more than four months.

M. Dufay, A. D. 1733.

While Mr Gray was pursuing his career of discovery in England, M. Dufay, of the Academy of Sciences, and superintendent of the Royal Botanic Gardens, was actively employed in the same researches. He found that all bodies, whether solid or fluid, could be electrified by an excited tube, by setting them on a glass stand slightly warmed, or only dried; and that those bodies which are in themselves least electrical, received the greatest degree of electricity from the approach of the glass tube. He found that electricity was transmitted more easily along packthread when it was wetted, and that it might be supported upon glass tubes in place of silk lines; and in this way he conveyed it along a string 1256 feet long.

M. Dufay repeated Mr Gray's experiments on the human body, by suspending a child on silken strings; but having suspended himself in a similar manner, he discovered that an electrical spark, accompanied with a crackling noise, took place when any other person touched him, and he has described the prickling sensation like the burning from a spark of fire, which is at the same time felt either through the clothes or on the skin. He found that the same effects took place in other living animals; but that if the carcass of an animal was suspended, there were no snippings or sparks, but merely a still uniform light observed in the dark.

Vitreous and resinous electricity.

The great discovery of M. Dufay, however, was that of two different kinds of electricity, to which he gave the name of *vitreous* and *resinous*, and the importance of which he did not fail to recognise. He has given the name of *vitreous* electricity to that which is produced by exciting *glass*, rock crystal, precious stones, hair of animals, wool, and many other bodies; and the name of *resinous* to that which is produced by exciting resinous bodies, such as amber, copal, gum-lac, silk, paper, thread, and a number of other substances. The characteristic of those two electricities was, that a body with *vitreous electricity* attracted all bodies with *resinous electricity*, and repelled all bodies with *vitreous electricity;* while a body with *resinous electricity* attracted all bodies with *vitreous electricity*, and repelled all bodies with *resinous electricity.* Two electrified silk threads, for example, repel each other, and also two electrified woollen threads; but an electrified silk thread will attract an electrified woollen thread. Hence it is easy to determine whether any body possesses vitreous or resinous electricity. If it *attracts* an electrified silk thread, its electricity will be vitreous; if it *repels* it, it will be resinous. This important discovery seems to have been made about the same time by Mr White, by a series of independent observations.

Mr Gray repeated and varied the experiments of M. Dufay, and made many new ones, which our limited space will not permit us to detail. Like Hawksbee and Dr Wall, he recognised the similarity between the phenomena of electricity and those of thunder and lightning; and he expresses a hope "that there may be found out a way to collect a greater quantity of electric fire, and consequently to increase the force of that power, which, by several of these experiments, *si licet magnis componere parva*, seems to be *of the same nature with thunder and lightning*."

Labours of continental philosophers.

The discoveries which we have now recounted began to rouse the activity of the German and Dutch philosophers. To the electrical machine used by Newton and Hawksbee, Professor Boze of Wittemberg added the *prime* conductor, which at first consisted of an iron or tin tube supported by a man standing upon cakes of rosin; but it was afterwards suspended by silken strings. Professor Winkler of Leipsic substituted the *cushion* in place of the hand for exciting the revolving globe; and Professor Gordon of Erfurt, a Scotch Benedictine monk, first used a glass cylinder, eight inches long and four broad, which he caused to revolve by means of a bow and string. By these means electrical sparks of great size and intensity were produced, and by their aid various combustible substances, both fluid and solid, were inflamed. In 1744 M. Ludolph of Berlin succeeded in firing, by the electrical spark, the ethereal spirit of Frobenius. Winkler did the same by a spark from his finger; and he succeeded in inflaming French brandy and other weaker spirits after they had been heated. Mr Gordon kindled spirits by a jet of electrified water. Dr Miles inflamed phosphorus by the electric spark; and oil, pitch, and sealing-wax, when strongly heated, were set on fire by similar means.

Leyden phial, 1745.

These striking effects were all produced by the electricity obtained immediately from an excited electric; but a great step was now made in the science by the discovery of a method of accumulating and preserving the electric fluid in large quantities. The author of this great invention is not distinctly known; but there is reason to believe that a monk of the name of Kleist, a person of the name of Cuneus, and Professor Muschenbroeck of Leyden, had each the merit of an independent inventor. The invention by which this accumulation was effected was called the *Leyden Jar* or *Phial*, because it was principally in that city where it was either invented or tried. Having observed that excited electrics soon lost their electricity in the open air, and that their loss was accelerated when the atmosphere was charged with moisture or other conducting materials, Muschenbroeck conceived that the electricity of bodies might be retained by surrounding them with bodies which did not conduct it. In putting this idea to the test of experiment, they electrified some water in a glass bottle, and a communication having been made between the water and the prime conductor, while the bottle was held by an assistant, who was trying to disengage the communicating wire, he received a sudden shock in his arms and breast, and thus established the efficacy of the Leyden jar.

Sir William Watson.

Sir William Watson made some important experiments at this period of our history. He succeeded in firing gunpowder by the electric spark; and by mixing the gunpowder with a little camphor he discharged a musket by the same power. He also fired inflammable air by the electric spark; and he kindled both spirits of wine and inflammable air by means of a drop of cold water, and even with ice. In the German experiments the fluid or solid to be inflamed was set on fire by an electrified body; but Sir William Watson placed the fluid in the hands of an electrified person, and set it on fire by causing a person not electrified to touch it with his finger.

Sir William Watson first observed the flash of light which attends the discharge of the Leyden phial, and it is to him that we owe the present improved form of the Leyden phial, in which it is coated both without and within with tinfoil. Dr Bevis indeed had suggested the outside coating, and, at Mr Smeaton's recommendation, he coated a pane of glass on both sides, and within an inch of the edge, with tinfoil; but still the idea of coating the jar doubly belongs to Sir William Watson.

Exper ments the R Societ Londo

A party of the Royal Society, with the president at their head, and Sir William Watson as their chief operator, entered upon a series of magnificent experiments, for the purpose of determining the velocity of the electric fluid, and the distance to which it could be conveyed. The French sçavans had conveyed the influence of the Leyden jar through a circuit of 12,000 feet; and in one case the basin at the Thuilleries, containing about an acre of water, formed part of the circuit; but the English philosophers made a more complete series of experiments, of which the following were the results:

1. That in all their operations, when the wires have been properly conducted, the electrical commotions from the charged phial have been very considerable only when the observers at the extremities of the wire have touched some substance readily conducting electricity with some part of their bodies.

2. That the electrical commotion is always felt most sensibly in those parts of the bodies of the observers which are between the conducting wires and the nearest and the most non-electric substance; or, in other words, so much of their bodies as comes within the electrical circuit.

3. That on these considerations we infer that the electrical power is conducted between these observers by any non-electric substances which happen to be situated between them, and contribute to form the electrical circuit.

4. That the electrical commotion has been perceptible to two or more observers at considerable distances from each other, even as far as two miles.

5. That when the observers have been shocked at the end of two miles of wire, we infer that the electrical circuit is four miles, viz. two miles of wire, and the space of two miles of the non-electric matter between the observers, whether it be water, earth, or both.

6. That the electrical commotion is equally strong, whether it is conducted by water or dry ground.

7. That if the wires between the electrifying machine and the observers are conducted on dry sticks, or other substances non-electric in a slight degree only, the effects of the electrical power are much greater than when the wires in their progress touch the ground, or moist vegetables, or other substances in a great degree non-electric.

8. That by comparing the respective velocities of electricity and sound, that of electricity, in any of the distances yet experienced, is nearly instantaneous.

In the following year these experiments were resumed with the view of ascertaining the absolute velocity of electricity at a certain distance, and it was found, "that through the whole length of a wire 12,276 feet, the velocity of electricity was instantaneous."

One of the most important discoveries of the present period was that of Sir W. Wtsoan, who proved "that the glass tubes and globes had not the electrical power in themselves, but only served as the first movers or determiners of that power." In rubbing a glass tube while standing upon a cake of wax, he was surprised to observe that no spark could be obtained from his body by any other person touching any part of him. But if a person not electrified held his hand near the tube while it was rubbing, the snapping was very sensible. The great discovery of *plus* and *minus* electricity which was afterwards made by Franklin, was distinctly announced by Sir W. Watson. He lays it down as a law, that in electrical operations there is an afflux of electric fluid to the globe and the conductor, and also an efflux of the same matter from them. In the case of two insulated persons, the one in contact with the rubber and the other with the conductor, he observed that either of them would communicate *a much stronger spark to the other than to any bystander. The electricity of the one,* he says, *became more rare than it is naturally, and that of the other more dense,* so that the density of the electricity in the two insulated persons differed more than that between either of them and a bystander.

Our limits will not permit us to give a detailed account of the various ingenious experiments which were about this time made by Le Monnier, Nollet, Winckler, Ellicott, Jallabert, Boze, Menon, Smeaton, and Miles. In 1746 Le Monnier confirmed the result previously obtained by Mr Gray, that electricity is communicated to homogeneous bodies in proportion to their surfaces only. M. Boze discovered that capillary tubes which discharged water by drops afforded a continued stream when electrified. The Abbé Nollet ascertained that electricity increases the natural evaporation of fluids, and that the evaporation is hastened by placing them in non-electric vessels. M. Jallabert confirmed the result previously obtained by Watson, that electricity passes through the substance of a conducting wire, and not along its surface. Smeaton found that the red-hot part of an iron bar could be as strongly electrified as the cold parts on each side of it. Dr Miles kindled common lamp spirits by a stick of black sealing-wax excited by dry flannel. Mr Ellicott conceived that the particles of the electric fluid repel each other, while they attract those of all other bodies. Mr Mowbray discovered that the vegetation of two myrtles was hastened by electrifying them; a result which Nollet confirmed in the case of vegetating seeds. The Abbé Menon found that cats, pigeons, sparrows, and chaffinches, lost weight by being electrified for five or six hours, and that the same result was true of the human body; and hence it was concluded that electricity augments the insensible perspiration of animals.

o-
es of
klin,
A 1747–

Passing over the scientific fables of John Pivati of Venice, we arrive at that auspicious period when Dr Franklin raised electricity to the dignity of a science, and connected it with that tremendous agency which had so often terrified the moral and convulsed the physical world. The thunderbolt had frequently descended from heaven upon its victims; but mortal genius had now learned to bring it down in chains, to disarm its fury, and to convert it into an useful and even a friendly element.

One of the first labours of the American philosopher was to present, in a more distinct form, the theory of plus and minus electricity, which Sir W. Watson had been the first to suggest. He showed that electricity is not created by friction, but merely collected from its state of diffusion through other matter by which it is attracted. He asserted that the glass globe, when rubbed, attracted the electrical fire, and took it from the rubber, the same globe being disposed, when the friction ceases, to give out its electricity to any body which has less. In the case of the charged Leyden jar, the inner coating of tinfoil had received more than its ordinary quantity of electricity, and was therefore electrified *positively* or *plus,* while the outer coating of tinfoil having had its ordinary quantity of electricity diminished, was electrified *negatively* or *minus.* Hence the cause of the shock and spark when the jar is discharged, or when the superabundant plus electricity of the inside is transferred by a conducting body to the defective or minus electricity of the outside. This theory of the Leyden phial Franklin established in the clearest manner, by showing that the outside and the inside coating possessed opposite electricities, and that, in charging it, exactly as much electricity is added on one side as is subtracted from the other. The copious discharge of electricity by points was observed by Franklin in his earliest experiments, and also the power of points to conduct it copiously from an electrified body. Hence he was furnished with a simple method of collecting electricity from other bodies; and he was thus enabled to perform those remarkable experiments which we shall now proceed to explain.

Hawksbee, Wall, and Nollet had successively suggested the similarity between lightning and the electric spark, and between the artificial snap and the natural thunder. Previous to the year 1750 Dr Franklin drew up a statement, in which he showed that all the general phenomena and effects which were produced by electricity had their counterpart in lightning. Like the electric spark, lightning moves in a crooked and irregular direction. Lightning strikes the highest and most pointed bodies, and electricity does the same. They both inflame combustibles, fuse metals, destroy animal life, produce blindness in animals, render common sewing needles magnetic, and reverse the polarity of needles that have been magnetised. Notwithstanding these points of resemblance, direct experiment was still necessary to establish his views. He waited anxiously for the erection of a spire at Philadelphia, by means of which he might bring down the electricity of a thunder-storm; but his patience being exhausted, he conceived the idea of sending up a kite among the clouds themselves. With this view he made a small cross of two light strips of cedar, the arms being sufficiently long to reach to the four corners of a large thin silk handkerchief when extended. The corners of the handkerchief were tied to the extremities of the cross, and when the body of the kite was thus formed, a tail, loop, and string were added to it. The body was made of silk to enable it to bear the violence and wet of a thunder-storm. A very sharp pointed wire was fixed at the top of the upright stick of the cross, so as to rise a foot or more above the wood. A silk ribband was tied to the end of the twine next the hand, and a key suspended at the junction of the twine and silk. In company with his son, Franklin raised the kite like a common one, in the first thunder-storm, which happened in the month of June 1752. To keep the silk ribband dry, he stood within a door, taking care that the twine did not touch the frame of the door; and when the thunder-clouds came over the kite he watched the state of the string. A cloud passed without any electrical indications, and he began to despair of success. He saw, however, the loose filaments of the twine standing out every way, and he found them to be attracted by the approach of his finger. The suspended key gave a spark on the application of his knuckle, and when the string had become wet with the rain, the electricity became abundant; a Leyden jar was charged at the key, and by the electric fire thus obtained spirits were inflamed, and all the other electrical experiments performed which had been formerly made by excited electrics. In subsequent trials with another apparatus, he found that the clouds were sometimes positively and sometimes negatively electrified, and thus demonstrated the perfect identity of lightning and electricity.

Having thus succeeded in drawing the electric fire from the clouds, Franklin immediately conceived the idea of protecting buildings from lightning, by erecting on their highest parts pointed iron wires or conductors communicating with the ground. The electricity of a hovering or a passing cloud would thus be carried off slowly and silently; and if the cloud was highly charged, the electric fire would strike in preference the elevated conductors.

Death of Professor Richman, A. D. 1753.

The attention of European philosophers was now directed to the great discovery of Franklin, and various individuals fearlessly sought to repeat his experiments. Among these Professor Richman of St Petersburg was one of the most enterprising. He had undertaken a series of experiments on the electricity of the atmosphere, and for this purpose he had erected an electrical gnomon, which consisted mainly of a Leyden jar, communicating with an iron rod, which rose four or five feet above the roof of his house, and an electrometer formed of a linen thread with half a grain of lead, the angular ascent of which on the face of a divided quadrant indicated the force of the accumulated electricity. On the 9th August 1752 Professor Richman obtained from the end of the rod electrical flashes which could be heard at several feet of distance; and if any person touched the apparatus, a sharp stroke was felt in the hand and arm. On the 31st May 1753 the electric fire exploded from the apparatus with such a force that it was heard at the distance of three rooms from the apparatus. On the 6th August 1753 the professor had prepared and adjusted his apparatus, and having heard the sound of distant thunder, he left a meeting of the Academy of Sciences, and took with him his engineer, Mr Sokolow, to draw any interesting phenomena that might occur. On their arrival at the professor's house, the plummet of the electrometer was elevated four degrees from the perpendicular; and while the philosopher was describing to his friend the dangerous consequences that might take place if the thread should rise to 45°, a tremendous burst of thunder terrified the imperial city. Richman leant his head over the gnomon to observe the indications of the electrometer, and in this stooping position, with his head a foot from the iron rod, a huge globe of bluish-white fire, about the size of Mr Sokolow's fist, shot from the iron rod to the professor's head, with a report like that of a pistol. The blow was fatal; he fell back upon a chest and instantly expired. Sokolow was stupified and benumbed by a sort of steam or vapour, and the red hot fragments of a metallic wire struck his clothes and covered them with burnt marks. As soon as he recovered from his surprise, Sokolow ran out of the house, acquainting every person with the accident which had taken place. In the mean time Madam Richman, alarmed by the thunder-stroke, hastened to the chamber, and found her husband apparently lifeless, in the attitude of sitting upon the chest, and leaning against the wall. Medical aid was instantly obtained, but though a vein was opened, from which no blood would flow, and though every attempt was made to restore life by violent friction and other means, they were all fruitless. A small quantity of blood dropped from the mouth when the body was turned, and on the forehead there was a red spot, from the pores of which a few drops of blood oozed out. Several red and blue spots, like leather shrunk by burning, were found on the left side, the back, and other parts of the body. The shoe upon the Professor's left foot was burst open, and a blue mark appeared on the foot beneath the aperture. There was no corresponding hole in the stocking, and the coat was uninjured. When the body was opened, twenty-four hours after death, there was no appearance of injury either in the brain or the cranium: a little extravasated blood appeared in the cavities below the lungs, and in the lungs towards the back, which were of a dark brown colour. The heart, glands, and smaller intestines, were all inflamed; but the entrails were uninjured. About seventy rubles of silver which were in the left coat pocket were not altered by the electric fluid. Immediately after the accident the house was filled with a sulphureous vapour. A clock which stood in the corner of the adjoining room was stopped; the ashes from the hearth were scattered about the room; the door-case of the room was rent asunder, and a piece of the door itself actually torn off. The Leyden jar was also broken, and the metallic filings which it contained thrown about the room.

Labou Canto A. D. 1

One of the most active and ingenious labourers in the field of electrical science was our countryman Mr John Canton. Before his time it had been assumed as indisputable that the same kind of electricity was invariably produced by the friction of the same electric; that glass, for example, yielded always *vitreous*, and amber always *resinous* electricity. Having roughened a glass tube by grinding its surface with emery and sheet lead, he found that it possessed vitreous or positive electricity when excited with oiled silk, but *resinous electricity when excited with new flannel.* He found, in short, that vitreous or resinous electricity may be developed at will in the same tube, by altering the surfaces of the tube and the exciting rubber, and according as the one or the other is most affected by their mutual friction. This he illustrated by the very beautiful experiment of removing the polish from one half of the tube. In this case the different electricities were excited with the same rubber at a single stroke, and, what is very curious, *the rubber was found to move much easier over the rough than over the polished half.*

Mr Canton likewise discovered that glass, amber, sealing-wax, and calcareous spar, were all electrified positively when taken out of mercury; and hence he was led to the important practical discovery, that an amalgam of mercury and tin was most efficacious in exciting glass when applied to the surface of the rubber. Mr Canton found also that any body placed within the electric atmosphere of another body acquired the electricity opposite to that of the body in whose atmosphere it was placed; and that the whole air of a room could be electrified either positively or negatively, and made to retain it for a considerable time.

Beccar A. D. 17

Signor Beccaria, a celebrated Italian, kept up the spirit of electrical discovery in Italy; and in his work on natural and artificial electricity, he has given us the results of many important original investigations. He showed that water is a very imperfect conductor of electricity, that its conducting power is proportional to its quantity, and that a small quantity of water opposes a powerful resistance to the electric fluid. He succeeded in making the electric spark visible in water, by discharging shocks through wires that nearly met in tubes filled with water. In this experiment the tubes, though sometimes eight or ten lines thick, were burst in pieces. Beccaria likewise demonstrated that air adjacent to an electrified body gradually acquired the same electricity; that the electricity of the body is diminished by that of the air; and that the air parts with its electricity very slowly. He considered that there was a mutual repulsion between the particles of the electric fluid and those of air, and that in the passage of the former through the latter a temporary vacuum was formed.

Symme experiments, A. D. 17

The science of electricity owes several practical as well as theoretical observations to our countryman Mr Robert Symmer. In pulling off his stockings in the evening, Mr Symmer had often remarked that they not only gave a crackling noise, but even emitted sparks in the dark. The electricity was most powerful when a silk and a worsted stocking had been worn on the same leg, and it was best exhibited by putting the hand between the leg and the stockings, and pulling them off together. The one stocking being then drawn out of the other, they appeared more or less inflated, and exhibited the attractions and repulsions of electrified bodies. Mr Symmer's first trials were accidentally made with *black* silk stockings, but he was surprised to find that *white* ones produced no electricity. Two white silk stockings, or two black ones, when put on the same leg and taken off, gave no electrical indications. When a black and a white stocking were put on the same leg, and at the end of ten minutes taken off, they were so much inflated when pulled asunder, *that each of them showed the entire shape of the leg, and at the distance of a foot and a half they rushed to meet each other.* With worsted stockings, also, nothing but the combination of black and white produced electricity. As it was troublesome to electrify the stockings by putting them on and taking them off the leg, Mr Symmer excited the stockings by drawing them on the hand, which, however, produced a weaker degree of electricity. The electricity was in this case more permanent, and the effects were more powerful, when the stockings were new or newly washed. When an excited white and black stocking are presented to each other, they attract one another, inclining to each other at the distance of three feet, catching hold of each other within two feet, and at a less distance rushing together with surprising violence, becoming as flat as so many folds of silk when they are joined. "But what appears most extraordinary is, that when they are separated, and removed at a sufficient distance from each other, their electricity does not appear to have been in the least impaired by the shock they had in meeting. They are again inflated, again attract and repel, and are as ready to rush together as before. When this experiment is performed with two black stockings in one hand, and two white in the other, it exhibits a very curious spectacle; the repulsion of those of the same colour, and the attraction of those of different colours, throws them into an agitation that is not unentertaining, and makes them catch each at that of its opposite colour, at a greater distance than one would expect. When allowed to come together, they all unite in one mass. When separated, they resume their former appearance, and admit of the repetition of the experiment as often as you please, till their electricity, gradually wasting, stands in need of being recruited."

In the course of these experiments Mr Symmer accidentally threw a stocking out of his hands, and some time afterwards he found it sticking to the paper hangings of the room. They stuck also to the painted pannelling, and often continued for a whole hour suspended upon the hangings.

Mr Symmer's attention was next directed to the force of cohesion between stockings of black and white silk, and he found that from ten ounces to nine pounds weight was necessary to separate the stockings, according to their weight, or according as the rough or smooth surfaces were in contact.

Mr Symmer likewise found that a Leyden jar could be charged by the stockings either positively or negatively, according as the wire from the neck of the jar was presented to the black or white stockings. When the electricity of the white stocking was thrown into the jar, and on that the electricity of the black one, or *vice versa*, the jar will not be electrified at all. With the electricity of two stockings he charged the jar to such a degree that the shock from it reached both his elbows; and by means of the electricity of four silk stockings he kindled spirits of wine in a tea-spoon which he held in his hand, and the shock was at the same time felt from the elbows to the breast. Independent of these curious experiments, Mr Symmer had the merit of having first maintained the theory of two distinct fluids, not independent of each other, as Dufay supposed them to be, but co-existent, and, by counteracting each other, producing all the phenomena of electricity. He conceived that when a body is said to be *positively electrified*, it is not simply that it is possessed of a larger share of electric matter than in a natural state; nor, when it is said to be *negatively electrified*, of a less; but that, in the former case, it is possessed of a larger portion of one of these active powers, and in the latter, of a larger portion of the other; while a body, in its natural state, remains unelectrified, from an equal balance of these two powers within it.

Contemporary with Symmer were Delaval, Wilson, Cigna, Kinnersley, and Wilcke. M. Delaval found that the sides of vessels that were perfect conductors, were non-conductors, and that animal and vegetable bodies lost their conducting power when reduced to ashes. Mr Wilson discovered that when two electrics are rubbed together, the harder of the two is generally electrified positively, and the other negatively, but always with opposite electricities. Cigna made many curious experiments by using silk ribbands in place of the silk stockings of Symmer. Kinnersley, the friend of Franklin, made some important experiments on the elongation and fusion of iron wires, when a strong charge was passed through them in a state of tension; and Wilcke brought to light many new phenomena respecting the spontaneous electricity produced by the melting of electric substances.

Pyro-electricity of minerals.

The pyro-electricity of minerals, or the faculty possessed by some minerals of becoming electric by heat, and of exhibiting negative and positive poles, now began to attract the notice of philosophers. There is reason to believe that the *lyncurium* of the ancients, which, according to Theophrastus, attracted light bodies, was the *tourmaline*, a Ceylon mineral, in which the Dutch had early recognised the same attractive property, whence it got the name of *Aschentrikker*, or attracter of ashes. In 1717 M. Lemery exhibited to the Academy of Sciences a stone from Ceylon which attracted light bodies; and Linnæus, in mentioning the experiments of Lemery, gives the stone the name of *Lapis Electricus*. The Duke de Noya had heard at Naples that Count Pichetti had seen at Constantinople a stone called *tourmaline*, which attracted and repelled light bodies; and in 1758 he purchased some of them in Holland, and, assisted by MM. Daubenton and Adanson, he made a series of experiments with them, which were published separately.

Labours of Æpinus.

This curious subject, however, had engaged the attention of M. Æpinus, a celebrated German philosopher, who published an account of them in 1756. Hitherto nothing had been said respecting the necessity of heat to excite the tourmaline; but it was shown by Æpinus that a temperature between $99\frac{1}{2}$° and 212° of Fahrenheit was requisite for the development of its attractive powers. Mr Benjamin Wilson, Priestley, and Canton, continued the investigation; but it was reserved for the Abbé Haüy to throw much light on this curious branch of the science. He found that the electricity of the tourmaline decreased rapidly from the summits or poles towards the middle of the crystal, where it was imperceptible; and he discovered that if a tourmaline is broken into any number of fragments, when excited, each fragment has two opposite poles. Haüy discovered the same property in the Siberian and Brazilian topaz, borate of magnesia, mesotype, prehnite, sphene, and calamine. He also found that the polarity which minerals receive from heat has a relation to the secondary forms of their crystals, the tourmaline, for example, having its resinous pole at the summit of the crystal which has three faces, and its vitreous pole at the summit which has six faces. In the other pyro-electrical crystals above mentioned, Haüy has detected the same deviation from the rules of symmetry in their secondary crystals which occurs in tourmaline. Mr Brard discovered that pyro-electricity was a property of the axinite; and more recently Sir David Brewster has detected it, as we shall afterwards see, in a variety of other minerals.

In repeating and extending the experiments of Haüy, Sir David Brewster discovered that various artificial salts were pyro-electrical; and he mentions the tartrate of potash and soda, and the tartaric acid, as exhibiting this property in a very strong degree. He likewise made many experiments with the tourmaline when cut into thin slices, and reduced to the finest powder, in which state each atom preserved its pyro-electricity; and he has shown that *scolezite* and *mesolite*, even when deprived of their water of crystallization, and reduced to powder, preserve their property of becoming electrical by heat. When this white powder is heated and stirred about by any substance whatever, it collects in masses like new fallen snow, and adheres to the body with which it is stirred.

Experiments of Æpinus.

In addition to his experiments on the tourmaline, Æpinus made several on the electricity of melted sulphur; and, in conjunction with Wilcke, he investigated the subject of electric atmospheres, and discovered a beautiful method of charging a plate of air by suspending large wooden boards coated with tin, and having their surfaces near each other, and parallel. Æpinus, however, has been principally distinguished by his ingenious theory of electricity, which he has explained and illustrated in a separate work which appeared at St Petersburg in 1759. This theory is founded on the following principles. 1. The particles of the electric fluid repel each other with a force decreasing as the distance increases. 2. The particles of the electric fluid attract the particles of all bodies, and are attracted by them, with a force obeying the same law. 3. The electric fluid exists in the pores of bodies; and while it moves without any obstruction in non-electrics, such as metals, water, &c., it moves with extreme difficulty in electrics, such as glass, rosin, &c. 4. Electrical phenomena are produced, either by the transference of the fluid from a body containing more to another containing less of it, or from its attraction and repulsion when no transference takes place.

Electricity of fishes.

The electricity of fishes, like that of minerals, now began to excite very general attention. The ancients, as we have seen, were acquainted with the benumbing power of the torpedo, but it was not till 1676 that modern naturalists attended to this remarkable property. The Arabians had long before given this fish the name of *raad* or lightning; but Redi was the first who communicated the fact that the shock was conveyed to the fisherman by means of the line and rod which connected him with the fish. Lorenzini published engravings of its electrical organs; Reaumur described the electrical properties of the fish; Kæmpfer compared the effects which it produced to lightning; but Bancroft was the first person who distinctly suspected that the effects of the torpedo were electrical. In 1773 Mr Walsh and Dr Ingenhouz proved, by many curious experiments, that the shock of the torpedo was an electrical one; and Dr Hunter examined and described the anatomical structure of its electrical organs. Humboldt, Gay Lussac, and M. Geoffroy, pursued the subject with success; and Mr Cavendish constructed an artificial torpedo, by which he was able to produce artificially the actions of the living animal. The subject has been more recently investigated by Dr Todd, Sir Humphry Davy, and Dr John Davy.

The power of giving electric shocks has been discovered also in the *Gymnotus Electricus*, the *Silurus Electricus*, the *Trichiurus Indicus*, and the *Tetraodon Electricus*. The most interesting and the best known of these singular fishes is the *Gymnotus* or Surinam eel. Its electrical organs have been minutely described by Hunter and Geoffroy; Dr Williamson, Dr Gordon, and Mr Walsh have published interesting details of its electrical powers; and Humboldt has more recently given the most romantic account of the combats which are carried on in South America between the gymnoti and the wild horses in the vicinity of Calabozo.

Mr Ca
dish, b
1731, d
1810.

Among the modern cultivators of electricity, our countryman, the late Mr Cavendish, is entitled to a distinguished place. Before he had any knowledge of the theory of Æpinus, he had composed and communicated to the Royal Society a theory of electrical phenomena nearly the same as that of the German philosopher. As Mr Cavendish, however, had carried the theory much farther, and considered it under a more accurate point of view, he did not hesitate to give his paper to the world.

Mr Cavendish made some accurate experiments on the relative conducting power of different substances. He found that the electric fluid experiences as much resistance in passing through a column of water one inch long, as it does in passing through an iron wire of the same diameter 400,000,000 inches long, and hence he concludes that rain or distilled water conducts 400,000,000 times more than iron wire. He found that the water, or a solution of one part of salt in one of water, conducts a hundred times better than fresh water; and that a saturated solution of sea-salt conducts seven hundred and twenty times better than fresh water. Mr Cavendish likewise determined by nice experiments that the quantity of electricity in coated glass of a certain area increased with the thinness of the glass; and that in different coated plates the quantity was as the area of the coated surface directly, and as the thickness of the glass inversely.

Chemic
electric

Although electricity had been employed as a chemical agent in the oxidation and fusion of metals, yet it is to Mr Cavendish that we owe the first of those brilliant enquiries which have done so much for the advancement of modern chemistry. By means of the electric spark he succeeded in decomposing atmospheric air. By using different proportions of oxygen and hydrogen, and examining the product which they formed after explosion with the electric spark, he obtained a proportion when the product was pure water. He was equally successful in the more difficult experiment of exploding oxygen and nitrogen; but when he combined seven measures of oxygen with three measures of nitrogen, he obtained from their explosion *nitric acid*. As several foreigners had failed in repeating this interesting experiment, Mr Cavendish, aided by Mr Gilpin, exhibited it publicly before the leading members of the Royal Society on the 6th of December 1787.

The decomposition of water by the electric spark was first effected by MM. Paets, Troostwyk, and Deiman; and improved methods of doing it were discovered and used by Dr Pearson, Mr Cuthbertson, and Dr Wollaston.

Galvan
and Vo
taic ele
tricity.

As a chemical agent, however, electricity was now destined to transfer its supremacy to another science. The great discovery made by Galvani in 1790, that the contact of metals produced muscular contraction in frogs, and the invention of the Voltaic pile, in 1800, by M. Volta of Como, have led to the establishment of a new science, called *Galvanism* or *Voltaic Electricity*, which, though now proved to be identical with common electricity, requires to be treated in a separate article. The chemical effects of the Voltaic pile far transcended those of ordinary electricity, and enabled Sir Humphry Davy to decompose the earths

History.

and the alkalies, and thus to create a new epoch in the history of chemistry.

Coulomb, born 1736, died 1806.

Contemporary with Mr Cavendish was M. Coulomb, one of the most eminent experimental philosophers of the last century. Anxious to determine the law of electrical action, he invented for this purpose an instrument called a *torsion balance*, which has since his time been universally used in all delicate researches, and which is particularly applicable to the measurement of electrical and magnetical actions. Æpinus and Cavendish had considered the action of the electrical fluid as diminishing with the distance; but M. Coulomb proved, by a series of elaborate experiments, that it varied like gravity in the inverse ratio of the square of the distance. Our countryman Dr Robison had previously determined, without, however, having published his experiments, that in the mutual repulsion of two similarly electrified spheres, the law was slightly in excess of the inverse duplicate ratio of the distance, while in the attraction of oppositely electrified spheres the deviation from that ratio was in defect; and hence he justly concluded that the law of electrical action was similar to that of gravity.

Adopting the hypothesis of two fluids, Coulomb investigated experimentally and theoretically the distribution of electricity on the surface of bodies. He determined the law of its distribution between two conducting bodies in contact; he measured the density of the electricity in different points of two globes in contact; he ascertained the distribution of electricity among several globes (whether equal or unequal) placed in contact in a straight line; he measured the distribution of electricity on the surface of a cylinder, and its distribution between a globe and cylinder of different lengths but of the same diameter. His experiments on the dissipation of electricity possess also a high value. He found that the momentary dissipation was proportional to the degree of electricity at the time; and that when the electricity was moderate, its dissipation was not altered in bodies of different kinds or shapes. The temperature and pressure of the atmosphere did not produce any sensible change; but the dissipation was nearly proportional to the cube of the quantity of moisture in the air. In examining the dissipation which takes place along imperfectly insulating substances, he found that a thread of gum-lac was the most perfect of all insulators; that it insulated ten times better than a dry silk thread; and that a silk thread covered with fine sealing-wax insulated as powerfully as gum-lac when it had four times its length. He found also that the dissipation of electricity along insulators was chiefly owing to adhering moisture, but in some measure also to a slight conducting power.

Experiments of Laplace, Lavoisier, and Volta, [illegible]

Towards the end of the last century a series of experiments was made by MM. Laplace, Lavoisier, and Volta, from which it appeared that electricity is developed when solid or fluid bodies pass into the gaseous state. The bodies which were to be evaporated or dissolved were placed upon an insulating stand, and made to communicate by a chain or wire with a Cavallo's electrometer, or with Volta's condenser, when it was suspected that the electricity increased gradually. When sulphuric acid diluted with three parts of water was poured upon iron filings, inflammable air was disengaged with a brisk effervescence; and at the end of a few minutes the condenser was so highly charged as to yield a strong spark of negative electricity. Similar results were obtained when charcoal was burnt on a chafing dish, or when fixed air or nitrous gas was generated from powdered chalk by means of the sulphuric and nitrous acids.

Volta.

M. Volta, who happened to be at Paris when these experiments were made, and who took an active part in them, had subsequently observed that the electricity produced by evaporation was always negative. He found that burning charcoal gives out negative electricity; and in other kinds of combustion he obtained distinct electrical indications.

Saussure.

In this state of the subject M. Saussure undertook a series of elaborate experiments on the electricity of evaporation and combustion. In his first trials he found that the electricity was sometimes positive and sometimes negative when water was evaporated from a heated crucible of iron; but he afterwards found it to be always positive both in an iron and a copper crucible. In a silver and in a porcelain crucible the electricity was negative. The evaporation of alcohol and of ether in a silver crucible also gave *negative* electricity. M. Saussure made many fruitless trials to obtain electricity from combustion, and he likewise failed in his attempts to procure it from evaporation without ebullition.

Many valuable additions were about this time made to electrical apparatus, as well as to the science itself, by Van Marum, Cavallo, Nicholson, Cuthbertson, Brooke, Bennet, Read, Morgan, and Henley; but our limits will not permit us to do any thing more than thus notice their labours.

Application of analysis to electricity.

The application of analysis to electrical phenomena may be dated from the commencement of the present century. Coulomb had considered only the distribution of electricity on the surface of spheres; but Laplace undertook to investigate its distribution on the surface of ellipsoids of revolution, and he showed that the thickness of the coating of fluid at the pole was to its thickness at the equator as the equatorial is to the polar diameter, or, what is the same thing, that the repulsive force of the fluid, or its tension at the pole, is to that at the equator as the polar is to the equatorial axis.

M. Biot.

M. Biot has extended this investigation to all spheroids differing little from a sphere, whatever may be the irregularity of their figure. He likewise determined analytically that the losses of electricity form a geometrical progression when the two surfaces of a jar or plate of coated glass are discharged by successive contacts; and he found that the same law regulates the discharge when a series of jars or plates are placed in communication with each other.

M. Poisson.

It is to M. Poisson, however, that we are mainly indebted for having brought the phenomena of electricity under the dominion of analysis, and placed it on the same level as the more exact sciences. By assuming the hypothesis of two fluids, he has deduced theorems for determining the distribution of the electric fluid on the surface of two conducting spheres when they are either placed in contact or at any given distance; and the truth of these theorems has been established by experiments performed by Coulomb long before the theorems themselves had been investigated.

Oersted's discovery of electro-magnetism, 1820.

The cultivation of the new science of Voltaic electricity had now withdrawn the attention of experimental philosophers from that of ordinary electricity. The splendour of its phenomena, as well as its association with chemical discovery, contributed to give it popularity and importance; but the discoveries of Galvani and Volta were destined, in their turn, to pass into the shade, and the intellectual enterprise of the natural philosophers of Europe was directed to new branches of electrical and magnetical science. Guided by theoretical anticipations, Professor H. C. Oersted of Copenhagen, in 1820, laid the foundations of the science of *Electro-magnetism*. He found that the electrical current of a galvanic trough, when made to pass through a platina wire, acted upon a compass needle placed below the wire; and upon repeating the experiment, he discovered the fundamental law, that *the magnetical effect of the Voltaic current had a circular motion round the current*, or round the *conductor*, or the wire through which the current passed. M. Ampere of Paris soon afterwards made the important discovery, that two wires conducting electrical currents, when suspended so as to be capable of motion, *attracted* each other when the currents moved in the *same direction*, and *repelled* each other when they moved in *opposite* directions; or, to express the fact more simply, *two points of electrical currents repel each other by their similar sides, and attract each other by their opposite sides;* so that, as Professor Oersted remarks, *an electric current contains a revolving action, exhibiting every appearance of polarity.*

Discoveries of Ampere.

Discoveries of Arago, Davy, and Seebeck.

In 1820 M. Arago, Sir H. Davy, and Dr Seebeck of Berlin, without being acquainted with each other's labours, discovered the power of the electric current to impart magnetism to iron and steel needles; but the most singular discovery on this branch of the subject was made by M. Savary, who found that small steel needles placed at different but very short distances from a wire conducting an electrical current, are magnetised in different directions. Needles in contact with the wire are magnetised in the usual or *positive* direction; while needles at the distance of 1·1 millimeter, or $\frac{1}{24}$th of an inch, are magnetised in an opposite direction, which he calls *negative.* At the distance of two inches from the wire there was a neutral line in which the needles were not magnetised at all. When the distance of the unmagnetised needle was increased from three to eight millimeters it again became positively magnetic, the maximum effect taking place at the distance of $5\frac{1}{2}$ millimeters. Between the distance of 8·6 and 21·4 millimeters the magnetism was a second time negative, the effect increasing from 8·6 to 14·6, and again reaching the vertical or zero point at 21·4. Beyond the distance of twenty-three millimeters the magnetism was again positive. With different conducting wires M. Savary found, that within certain limits the maximum intensity is produced at a greater distance from the wire, and the number of alternations of positive and negative direction is also greater in proportion, as the wire is shorter in proportion to the length of the helix. When needles are placed parallel to the axis of a helix of narrow windings, they all receive the same kind of magnetism; but when the electrical charge is increased from one jar to a battery of twenty-two superficial feet, six alternations, viz. three positive and three negative, are obtained. When Voltaic electricity is substituted for ordinary electricity, the alternations are destroyed by a continued current, but appear when the current is established only for an instant.

Discoveries of M. Savary.

Discoveries of Professor Erman.

These curious experiments were followed by those of Professor Erman of Berlin, who found that when an electrical discharge passes through the centre of a circular disc of steel, and in a line perpendicular to its surface, no apparent magnetism is developed; but when a slit is made in the plate, or a sector cut out of it, the side of the disc opposite to the slit, or the sectoral opening, exhibits the opposite magnetism. MM. Gay Lussac and Welther obtained the same result with a steel ring.

Discoveries of Dr Seebeck, 1822.

The discovery of thermo-electricity by Dr Seebeck in 1822 gave a new impulse to this branch of science. In studying the influence of heat in Galvanic arrangements, he was led to believe that magnetism might be developed in two metals forming a circuit when the equilibrium of heat in them was disturbed. He accordingly joined a semicircular piece of bismuth with a similar piece of copper, so as to form a circle by their union; and when one of the junctions was heated an electrical current was produced, which could show its existence only by the magnetic needle, and which exhibited all the magnetical properties of an electrical current.

Dr Fa day's c coveri

In the same year in which Dr Seebeck made this remarkable discovery, the rotation of a magnetical needle round an electrical current, and of a body transmitting an electrical current round a magnet, were exhibited in a series of beautiful and highly ingenious experiments by Dr Faraday, whose subsequent discoveries place him at the head of the cultivators of this most interesting science.

Exper ments Arago others

These experiments were followed by those of Arago, Barlow, Seebeck, Herschel, and Babbage, in which a revolving plate of copper gives a rotatory motion to a magnetic needle conveniently suspended; but notwithstanding the ingenuity and talent with which this subject was treated by these eminent individuals, it is to Dr Faraday that we owe a complete analysis and explanation of this curious phenomenon.

Disco of ma to-ele city b Farad

This explanation was founded on the great discovery of the evolution of electricity from magnetism, by which Dr Faraday laid the foundation of the new science of magneto-electricity. By means of a series of simple and beautiful experiments with the celebrated magnets of Dr Godwin Knight, and with the powerful magnet of Professor Daniel, Dr Faraday obtained the most unequivocal and striking electrical effects, though the intensity of the electricity was very feeble, and its quantity small. He obtained a distinct though feeble spark; he succeeded in convulsing the limbs of a frog by means of a magnet; and he perceived also the sensation on the tongue and the flash before the eyes, but he could not effect chemical decomposition by magnetism. Besides obtaining these important results, Dr Faraday has clearly established the laws according to which a magnet developes magnetic currents. He applies these laws to the explanation of the reciprocal action of revolving magnets and metals, and he adduces unquestionable proofs of the production of electricity by terrestrial magnetism.

These important results have been more recently extended by Dr Faraday and others. M. Pixii observed attractions and repulsions in the electricity evolved by magneto-electric induction; and by an ingenious and powerful apparatus he obtained a great degree of divergence in the gold leaves of an electrometer. At the meeting of the British Association at Oxford in June 1832, Dr Faraday, by means of Mr Snow Harris's electrometer, subsequently described, succeeded in heating a wire by magneto-electric induction. By means of the magneto-electric apparatus of M. Pixii already referred to, he and M. Hachette decomposed water, and obtained the oxygen and hydrogen in separate tubes.

Ident the va electr ties e blishe Dr Fa day.

In the progress of his electrical researches, Dr Faraday found it necessary for their further prosecution to establish either the identity or the distinction of the electricities excited by different means; and in a paper of great value, he has established beyond a doubt the identity of common electricity, Voltaic electricity, magneto-electricity, thermo-electricity, and animal electricity. The phenomena exhibited in these five kinds of electricity do not differ in kind, but merely in degree; *and in this respect they vary in proportion to the variable circumstances of quantity and intensity, which can at pleasure be made to change in almost any one of the kinds of electricity, as much as it does between one kind and another.* Dr Faraday has given the following interesting table of the experimental effects common to the electricities derived from different sources.[1]

---

[1] The cross indicates that the effect at the top of this table is produced by the electricity mentioned in the column at the side.

ion easure linary oltaic ricity.

Dr Faraday was anxious to determine the relation by measure of ordinary and Voltaic electricity; and after various excellent experiments, he obtained as an approximation, and judging from magnetical force only, "that two wires, one of platina and one of zinc, each one eighteenth of an inch in diameter, placed five sixteenths of an inch apart, and immersed to the depth of five eighteenths of an inch in acid consisting of one drop of oil of vitriol, and four ounces distilled water at a temperature about 60°, and connected at the other extremities by a copper wire eighteen feet long and one eighteenth of an inch thick (being the wire of the galvanometer coils), yield as much electricity in eight beats of my watch, or in $\frac{8}{150}$ths of a minute (or 3·2 seconds), as the electrical battery (of fifteen jars) charged by thirty turns of the large machine in excellent order. The same result was found to be true in the case of chemical force."

Fara- s new of elec- l con- ion.

In the course of his investigations relative to electro-chemical composition, Dr Faraday was led to observe the effects due to a very general law of electric conduction which had not formerly been recognised. He found that solid bodies assume the power of conducting electricity during liquefaction, and lose this conducting power during congelation. The Voltaic electricity produced by a battery of fifteen troughs, or a hundred and fifty pairs of four-inch plates powerfully charged, was incapable of passing through a thin film of ice three sixteenths of an inch thick; but when the ice was melted, the electricity passed in such quantities as to deflect the magnetic needle 70°. This insulation, however, exhibited by ice is not effective with electricity of exalted intensity. In making this experiment with other solid bodies, Dr Faraday chose those which, being solid, at common temperatures were fusible, and of such a composition as, for other reasons connected with electro-chemical action, led to the conclusion that they would be able to replace water. When the electric current passed through the solid body employed, there was no chemical decomposition; but when the body was liquefied or fused, the decomposition took place. The bodies which Dr Faraday found to be subject to this law will be found in our section on Electrical Conduction. The degree of conducting power conferred upon bodies by liquidity is generally very great. In water it is the feeblest of all; and in the various oxides, chlorides, salts, &c. it is given in a much higher degree, some a hundred times greater, than in the case of pure water.

cove- of M. tier.

Before we close this brief history of electrical discoveries, we must notice the very remarkable one communicated to the Academy of Sciences at Paris, on the 27th May 1833, by M. Peltier, who has announced that, without changing the producing cause, he can transform *quantity* of electricity into *intensity*, and *intensity* into *quantity*, and neutralise two similar currents, proceeding always from the same cause, by making them interfere in opposite directions.

Labours of Mr Snow Harris.

Among the able and active cultivators of electrical science, we must not omit the name of Mr Snow Harris of Plymouth. His beautiful instrument for measuring the heat evolved in electrical action,—his lightning conductors for ships,—his measuring electrometer,—his application of it in determining in a new way the law of electrical attraction, whether it takes place between simply electrified conductors, or between accumulated electricities,—his experiments on the action of spheres and planes, and bodies of other forms,—on the laws of electrical accumulations, and on the controlling power of bodies,—entitle him to a high place in the lists of electrical discovery.

PART I.

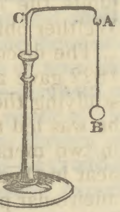
PHENOMENA AND LAWS OF ELECTRICITY.

Elementary Phenomena and Definitions.

Elementary phenomena and definitions.

1. If a smooth glass tube, or the glass of a watch, or a piece of sealing-wax, or amber, be rubbed upon the sleeve of a cloth coat, or, what is still better, if it be rubbed with a piece of dry flannel or woollen cloth, it will be found to have acquired from this friction a new physical property. This property will be exhibited by holding the body which has been newly rubbed above small shreds of paper, gold leaf, or any thin light bodies placed upon the table. These bodies will be instantly *attracted* to it, some of them adhering to its surface, others falling back to the table, and others being thrown off from the body as if they were repelled from it.

The property which has thus been communicated by friction is called *electricity*, the body which acquires the property is called the *electric*, the attraction which it exercises over light bodies is called *electric attraction;* and when the attractive power is produced by friction, the body *rubbed*, or the *electric*, is said to be *excited* by friction, and the body by which it is excited is called the *rubber*.



2. In order to study these phenomena with more precision, let a small ball B, the size of a pea, made of cork, or the dry pith of elder, or, what is better still, of the finely porous pith of the sola tree from India, be suspended from a stand ACD by a dry silk thread AB. Having rubbed a large glass tube with a piece of dry silk, present it to the ball B, and the ball will be instantly attracted to the tube, and will adhere to it. After they have continued in contact for a second or two, withdraw the glass tube, taking care not to touch the ball with the finger. If the excited glass tube is now a second time brought near the ball, the ball will recede from it, or will be *repelled* by the tube. If, after touching the ball

with the finger, so as to deprive it of its electricity, the above experiment is accurately repeated with a stick of *sealing-wax* in place of glass, the very same phenomena will be exhibited; the ball will, in the first instance, be *attracted*, and on the second application of the sealing-wax it will be *repelled*. Hence we draw two conclusions, *first*, that both *glass* and *sealing-wax* attract the ball B before they have communicated to it any of their own electricity; and, *second*, that both these electrics repel the ball after each of them has communicated to it some of their own electricity.

3. Let us now examine what takes place when the excited sealing-wax is presented to the ball, after the ball has received electricity from the excited glass, and *vice versa*. For this purpose excite the glass tube, present it to the ball B, and after it has been a few seconds in contact, withdraw it. The ball has now received electricity from the glass tube. Let the sealing-wax be now excited and presented to the ball, the ball, in place of being *repelled*, will be *attracted* by the wax. Reverse this experiment, by first presenting the excited wax to the ball, and then the excited glass, and it will be in like manner found that the glass *repels* the ball. Hence it follows that

Excited glass *repels* a ball electrified by excited glass.
Excited wax *repels* a ball electrified by excited wax.
Excited glass *attracts* a ball electrified by excited wax.
Excited wax *attracts* a ball electrified by excited glass.

From which we conclude that there are two opposite electricities, namely, that produced by excited glass, to which the name of *vitreous* or *positive* electricity has been given, and that produced by excited wax, to which the name of *resinous* or *negative* electricity has been given.

4. If, when the pith ball B is electrified, either with excited glass or wax, we touch it with a rod of glass, its property of being subsequently attracted or repelled by the excited glass or wax will suffer no change; but if we touch it with a rod of metal it will lose the electricity which it had received, and will be attracted both by the excited glass or wax, as it was when they were first applied to it. Hence the rod of glass and the rod of metal possess different properties, the former being incapable, and the latter capable, of carrying off the electricity of the pith ball. The metal is therefore said to be a *conductor*, and the glass a *non-conductor*, of electricity.

In the few elementary experiments which we have now described, the electricity has been produced by *friction*; but the pith ball could have been electrified by a great variety of other methods, which will be explained in a subsequent part of this article. In all these cases the effects are precisely the same, whatever be the source from which the electricity is obtained; but as friction is the simplest means of generating electricity, and as machines and apparatus have been invented, by means of which it can be thus produced in great abundance, and accumulated in great quantities, we shall proceed to describe the phenomena and laws of electricity as produced by friction.

CHAP. I.—ON THE PHENOMENA OF ELECTRICITY PRODUCED BY FRICTION.

SECT. I.—*Description of the Electrical Machine for generating Electricity.*

Although the friction produced by the strength of the human arm is sufficient to produce abundance of electricity for ordinary experiments, yet the aid of mechanism has been found essential for carrying on electrical investigations, and producing powerful electrical effects. The various forms which have been given to the electrical machine will be described in the second part of this article, under the head of Electrical Apparatus, so that we shall chiefly confine our attention at present to a description of the plate-glass machine.

Plate-g
machi
Pl. CC
Fig. 1.

This machine, in its common form, is represented in Plate CCIX. fig. 1, where AB is a circular disc of plate glass from eighteen inches to two or more feet in diameter, and from two to three eighths of an inch thick. This disc is fixed perpendicular to a horizontal axis, supported by two uprights E, F, of a mahogany frame, and is capable of being turned round with any ordinary degree of velocity, by means of the handle or winch W. The rubbers by which this disc of glass is rubbed or excited are placed at the upper and lower end of the disc, as seen in the section, fig. 2. The two upper rubbers above A, viz. G, H, are suspended from the top of the frame, and are fixed by screws to two flat pieces of wood *m*, *m*, which can be pressed together or slackened by turning the screw *s* so that the rubbers G, H may be made to press with the requisite degree of force against the disc AB which revolves between them. The lower rubbers M, N below B, are supported upon the stand, and are similarly put together. The rubbers are generally flat cushions of silk or soft leather stuffed with hair.

Rubbe

Prime
ductor

The prime conductor CD is a semicircle of hollow brass, supported on the upright E by means of the solid glass cylinder R. The two extremities of this conductor, one of which is seen below A, and the other above B, carry each a row of brass points, and the transverse piece of brass tube in which the points are inserted terminates in a varnished wooden ball.

Silk fl

From the upper rubbers an oil silk flap, embracing both surfaces of the plate, extends to a little above the row of points on the conductor; and from the lower rubbers a similar flap extends to a little below the other row of points. One of these flaps is seen in the figure, but the other is hid by the upright E.

Amalg

As it has been found that electricity is developed more copiously when the rubbers are covered with an amalgam of one part of tin and two of mercury, various compositions have been tried by philosophers. The following amalgam, recommended by Singer, is equal in efficacy to any that has yet been proposed. Melt two ounces of zinc and one of tin, and pour into the crucible six ounces of mercury. Shake the whole together till it is cold, in an iron or thick wooden box; and when it has been reduced to a fine powder in a mortar, mix it with as much lard as will form it into a paste. The amalgam thus formed must then be thinly spread on the surface of each cushion; and when the disc of glass has been well cleaned from dust, and from black specks or lines, by means of a little spirits of wine, the mixture is ready for use.

When a very powerful excitation is required, it is usual to cover a piece of smooth leather, four or five inches broad, with the amalgam, and apply it with the hand to the revolving disc; and it has been found very useful to apply previously a rag with a little tallow, so as just to give a slight dimness to the glass.

Rona
cylinc
machi
Fig. 3

Although the plate glass machine is generally regarded as the best, yet, from its greater cheapness and facility of construction, the cylinder machine is most commonly used. We shall therefore describe at present one of those machines as improved by Mr F. Ronalds. This machine is represented in fig. 3, where A is a cylinder of blue glass about a quarter of an inch thick, supported by the two mahogany uprights B, B, fixed to the box or case C, which forms the base of the machine. DD is a copper pipe which supports the semicylinder E, which is also hollow, and into which the pipe D opens. This semicylinder carries on its flat side the cushion or rubber, the surface of which is made concave to suit the convexity of the cylinder AA. A small spirit-lamp F, the burner of which consists only of a single cotton thread, is placed, as shown in the figure, immediately beneath the mouth of the copper pipe DD. The prime conductor G, which stands parallel to the cylinder, is a cylindrical tube of thin copper, rounded at both ends, and carrying at its middle a row of metallic points, which nearly touch the surface of the glass cylinder. The conductor G is supported by a hollow glass support H, opening into the hollow conductor G. Its lower end at H is fixed to the wooden case C by means of three screws, one of which is seen at *a* passing through a circular piece of hard boxwood, the inside of which, as well as that of the perforation in the case C, is lined with leather. The lower end of the glass tube H terminates, like that of D, within the case C, and a spirit-lamp is in like manner placed beneath it.

By these ingenious contrivances the rubber and the conductor[1] are kept warm and dry, and in damp weather, or in a close room, where the air is rendered moist by the breath of the audience, the machine will be found always effective and in working order. Mr Ronalds is of opinion that the excitation of the cylinder is promoted by the excitation of the amalgam by means of the heat. If similar means are not taken to heat the interior of the glass cylinder, the development of electricity may be promoted by holding a hot piece of cloth or flannel beneath the cylinder while it is in operation.

Sect. II.—*On the Phenomena of Electrical Attraction and Repulsion.*

If the electrical machine, when thus prepared, is put in motion, the two rows of points will collect the electricity which is generated by friction, and the brass conductor CD, fig. 1, will be filled with the electricity thus produced. By means of this electricity the following experiments may be readily performed.

Exp. 1. If we suspend a pith ball by a slender wire, and bring the ball near the conductor, it will be instantly attracted by, and adhere to, the conductor, as long as there is any electricity left. In this case the electricity imparted to the ball by the conductor is carried off by the conducting wire to the hand, and through the body to the earth.

If the pith ball is suspended by a dry silk thread, and held near the conductor, it will at first be attracted to it as formerly; but after it has received as much as it can take, it will then be repelled by the conductor, from the repulsive action of the two similar electricities, and it will not again approach the conductor, till either its own electricity or that of the conductor has been carried off by the contact of some conducting body. In either of these cases the pith ball will be again attracted by the conductor.

Exp. 2. Suspend a little brass ball by a silk thread, and bring the ball near the conductor, so as to receive electricity from it, and be repelled, as in experiment 1. Then with the other hand bring another brass ball near to the first, but on the side of it opposite to the conductor. The first ball will now be attracted to the conductor in consequence of having given out its electricity to the second ball; but having received a new charge of electricity, it will be repelled from the conductor and attracted to the hand or fixed ball. In this way it will oscillate like a pendulum between the conductor and the fixed ball. If in place of the fixed ball we substitute a bell, the ball will oscillate as before, and cause the bell to ring by its successive strokes.

Electrical bells.

Exp. 3. The beautiful experiment of the *electrical bells* is exhibited in fig. 4, where AB is a solid glass rod surmounted by a brass ball A, and supported upon a wooden stand. Two arms of brass crossing at right angles are also supported by the glass rod, and, by means of wires or chains hanging from their extremities, are suspended four bells *b*, *b*, *b*, *b*. From the middle part of each of these cross arms is suspended a brass ball by silk threads, so that each ball when put in motion and made to oscillate in a plane passing through its own cross arm, may strike alternately the middle bell b' and the one adjacent to it. If the brass ball is now placed close beneath the brass knob of the prime conductor, or made to communicate with it, the electricity of the conductor will be transmitted through the brass arms to the balls, and the balls giving out their electricity to the bells, will strike them alternately, and cause them to ring, the electricity passing off through the central bell b' into the earth.

The experiment may be made more simply by suspending three bells, one from the middle, and one from each extremity of a brass rod, which is hung by its middle part from an electrified conductor. Two brass balls are hung by a silk thread between the central bell and the outer ones. The outer bells are supported by a wire or chain, and the central one by a silk thread. This central bell, however, must communicate with the ground by a chain. When the machine is put in motion, the electricity passes to the outer bells, and the insulated balls, being attracted and repelled, strike the outer bells and the inner one, by which last the electricity passes into the earth.

A still simpler form of the experiment consists in placing two small bells on separate glass stands, at a quarter of an inch distance, one of the bells communicating with the prime conductor, and the other with the ground. A brass ball is then suspended between them by a silk thread, and when the machine is wrought, the electricity will pass to the earth through the bells and the ball, the latter oscillating between them, and ringing them, as long as the current of electricity is kept up.

Exp. 4. Take a dozen of threads about a foot long, and having tied them together at both ends, hang them, by a loop attached to the upper knot, to the prime conductor. When the machine is wrought, the threads will separate from each other, swell out at the middle, and assume a form approaching to that of a sphere. If the threads are merely joined at each end, so that their extremities point to two poles, which may easily be done, they would swell out, and form, as it were, the meridians of a hollow globe. This pretty experiment we owe to Mr Wheler.

Exp. 5. Having fastened a piece of sealing-wax to a wire, and inserted the wire in the hole at the end of the prime conductor, soften the sealing-wax by the flame of a candle, and work the machine;—fine fibres of wax like those of wool will be thrown off, and may be received on paper. By gently heating the paper, the result of the experiment may be fixed. These fibres are thrown off by the repulsion of the electrified particles of wax, which becomes a conductor when melted. The same experiment might no doubt be made with melted sugar, rosin, and other substances.

---

[1] It would be easy to improve this construction, by introducing the heated air of other two spirit-lamps into each end of the cylinder.

Fig. 5.

Exp. 6. The experiment of the dancing figures is one of the finest illustrations of electrical attraction and repulsion. Take two circular discs of wood or pasteboard, E, F, like those shown in fig. 5. Cover them with tinfoil, and having suspended the uppermost from the prime conductor (or from the end D of a metallic rod CD insulated by the glass stand AB, and whose other extremity C communicates by a chain with the prime conductor), place the other upon a stand G, so that, by means of the screw nut *n*, it can be raised or depressed. Place upon the lower disc small painted figures cut out of paper, and as soon as the machine is wrought the figures will spring upon their feet, and execute the most extraordinary movements, sometimes dancing on their heads, sometimes hanging by the upper plate, and sometimes flying into each other's arms. If these figures are cut out of the pith of the sola tree, and if the arms and legs are made separate, and attached by threads to the body, the effect surpasses all description. The circular discs will answer equally well if made of metal.

Exp. 7. Suspend from the prime conductor a small metallic cup nearly full of water, and having placed in it the shorter end of a syphon made with a capillary glass tube, of such a bore that the water will with difficulty drop from it. When the water is electrified by working the machine, it will be discharged in a continuous stream from the larger arm of the syphon; and if the electricity is powerful, the current of water will divide itself into several branches. In like manner, if a condensed air fountain is electrified, the jet will subdivide itself into minute parts, and suffer great expansion; but the moment the machine stops it resumes its original form. In like manner, if a sponge filled with water discharges the fluid only by drops, it will, when electrified, let fall an abundant shower, which in the dark will be luminous.

Exp. 8. In a metallic cup place a piece of lighted camphor, and when the cup communicates with the electrified conductor, the camphor will throw off numerous ramifications, shooting forth its branches like a vegetable in growth.

An immense number of similar experiments may be made by placing pith balls under inverted tumblers, and thin balls of glass within metallic rings; and when the tumblers and the rings are electrified, the most varied movements are produced; and the effect is greatly heightened by the accompanying luminosity, which displays itself in the dark.

The theory of the phenomena which we have now described will be given in a subsequent section.

SECT. III.—*On the Phenomena of Positive and Negative Electricity.*

Positive and negative electricity.

We have already seen that there are two opposition electricities, which have received the name of *positive* or *vitreous*, and *negative* or *resinous* electricity, the former being generated by excited *glass*, and the latter by excited *wax*.

In order to examine the properties of these two kinds of electricity, take four stands like that shown in page 575, consisting of a vertical rod of glass fixed in a wooden base. From the top of each stand suspend a single pith ball by a slender wire, and place the four stands, which we shall call P, P′ and N, N′ at some distance from each other on a table. Electrify the pith balls on P, P′ by excited glass, so as to make them *positively* electrical; and the pith balls on N, N′ with excited wax, so as to make them *negatively* electrical. The following phenomena will then be observed. If the balls P, P′ or N, N′ are brought near each other, they will *repel* one another, but if P or P′ is brought near to N or N′, the balls will attract each other. Hence it follows,

Propert of posit and neg tive ele tricity.

That two SIMILARLY *electrified bodies P, P′ or N, N′* REPEL *each other, while two* DISSIMILARLY *electrified bodies P, N or P′, N′* ATTRACT *each other.*

If, in place of electrifying the balls with the glass and the sealing-wax, we had electrified them with the rubber with which they had been excited, we should have found that the rubber which excited the glass gave out *resinous* electricity, and the rubber which excited the wax *vitreous* electricity. Hence we learn,

That in electrical excitation positive and negative electricity are simultaneously produced.

Pl. CC Fig. 6.

In all electrical machines, therefore, where the plate or cylinder is made of glass, the conductor which takes the electricity from the glass will be charged with *positive* electricity; and as the rubber is negatively electrified, we may obtain negative electricity from it in the same abundance, by placing a conductor behind the rubber, and insulating them both by a glass stand. In the cylinder machine this is easily done, as shown in fig. 6, which represents a machine driven by a wheel and pulley, where E is the negative conductor placed at the back of the rubber R, and S the glass stand by which they are both supported and insulated.

Van M rum's m chine, Pl. CC Fig. 1–

Dr Ha machin fig. 7.

In the plate-glass machine it is more difficult to unite a conductor to the rubbers. In Van Marum's beautiful electrical machine, shown in fig. 1–5 of Plate CCX. and which will be more minutely described afterwards, the *positive* and *negative* electricity can be obtained only in succession; but Dr Hare, of the university of Pennsylvania, has removed this difficulty by the very ingenious contrivance shown in fig. 7, of making the plate revolve horizontally, and thus allowing the positive and negative conductors B, F to stand like arches in two vertical planes at right angles to each other.

The circumstances of surface and structure under which bodies yield the two opposite electricities by friction are still very imperfectly understood. Mr Canton found that the same body gave out opposite electricities when rubbed with different substances. *Polished glass*, for example, was always *positively* electrified when excited with flannel or silk; but always *negatively* electrified when excited by the back of a cat. But, what was still more strange, he found that *rough glass* acquired *negative* electricity when excited by flannel, and *positive* electricity when excited by dry oiled silk. Rough quartz has been found to exhibit the same difference.

A still more extraordinary and instructive anomaly was observed by Haüy in exciting a mineral called *kyanite*. Some of the crystals he found to acquire positive electricity by friction, while others acquired negative electricity. Saussure had announced that they were negatively electrified by friction; and when Haüy obtained an opposite result in his first experiment, he was led to examine the subject more carefully, and to make his trials both with the natural faces and with those produced by cleavage. "I have," he remarks, "in my collection a crystal whose opposite faces have presented me with these opposite effects (*electricities*), and I can assign no other cause for this singular result than a certain alteration in the contexture of one of the surfaces." Hence Haüy has given the name of *disthene*, or *two powers*, to this mineral. The remarkable property which Haüy discovered in the individual crystal above referred to, may have arisen from some composite structure which he did not recognise.

As the property of giving positive or negative electricity by friction has been used as a mineralogical character, we shall lay before our readers a general view of the experiments which have been made on the subject, which we have collected from a great variety of sources.

Names of the Excited Substances.	Nature of the Electricity produced.	Substances used for Excitation.
Smooth glass	Positive	Every substance yet tried but the back of a cat and mercury.
	Negative	Back of a cat, and sometimes caoutchouc. (Nich. *Journ.* xxviii. p. 11.)
Rough glass	Positive	Dry oiled silk, metals, wax, and resinous matters.
	Negative	Woollen cloth, human hand, back of a cat, wood, paper, quills.
Quartz, smooth	Positive	Flannel, &c.
Quartz, rough	Negative	Flannel, &c.
Topaz, smooth	Positive	Flannel, &c.
Topaz, rough	Negative	Flannel, &c.
Back of a living cat	Positive	Every substance yet used.
Hare skin	Positive	Human hand, silk, leather, metals, paper, baked wood, and loadstone.
	Negative	Other finer furs.
White silk	Positive	Black silk, black cloth, metals.
	Negative	Human hand, weasel's skin, paper, hair.
Black silk	Positive	Sealing-wax.
	Negative	Hare's, weasel's, and ferret's skin, white silk, human hand, brass, silver, iron, loadstone.
Woollen cloth	Positive	Zinc, silver, bismuth, copper, lead, oligist iron.
	Negative	Platina, gold, tin, antimony, grey copper, grey cobalt, tellurium, &c.
Sealing-wax	Positive	Rough glass, white wax, sulphur, and all metals except iron, steel, plumbago, lead, and bismuth.
	Negative	Hare's, weasel's, and ferret's skin, human hand, leather, smooth glass, flannel, wood, paper, iron, steel, plumbago, lead, and bismuth.
Baked wood	Positive	Silk, paper, rough glass, wax, lead, sulphur, and the metals.
	Negative	Flannel, hare's skin, smooth glass, quills.
Sulphur	Positive	All metals but lead.
	Negative	Lead and all other substances.
Resinous bodies	Positive	All resinous substances.
	Negative	All bodies but resinous ones.

The most accurate and numerous observations on the development of electricity by friction were made by the Abbé Haüy in reference to the discovery of new characters of minerals. He rubbed the minerals on a woollen cloth, and when it was necessary to insulate them he fixed them by wax to the end of a stick of gum-lac or Spanish wax. In this way he divided the mineral kingdom into four classes of bodies in reference to the electrical character of the minerals.

Class I.—*Containing minerals which possess the insulating property,*[1] *and acquire vitreous electricity by friction.*

Boracite.
Topaz.
Axinite.
Tourmaline.
Mesotype.
Prehnite.
Oxide of zinc.
Sphene.
Carbonate of lime.
Carbonate of magnesia.
Arragonite.
Apatite.
Fluate of lime.
Gypsum.
Anhydrite.
Sulphate of barytes.
Sulphate of strontian.
Carbonate of barytes.
Carbonate of strontian.
Sulphate of magnesia.
Siliceous borate of lime.
Nitrate of potash.
Sulphate of potash.
Muriate of soda.
Glauberite.
Hyalin quartz.
Zircon.
Corundum.
Cymophane.
Spinelle.
Emerald.
Euclase.
Cordierite.
Garnet.
Essonite.
Idocrase.
Feldspar.
Apophyllites.
Actinote.
Tremolite.
Diopside.
Epidote.
Stilbite.
Analcime.
Nepheline.
Kyanite.
Mica.
Macle.
Talc transp.
Diamond.
Carbonate of lead.
Sulphate of lead.
Tungstate of lead.
Carbonate of zinc.
Oxide of tin.

Class II.—*Containing minerals which possess the insulating property (excepting anthracite), and acquire resinous electricity by friction.*

Sulphur.
Bitumen.
Retinasphaltum.
Amber.
Mellite.
Anthracite.

Class III.—*Containing conducting substances which acquire, when they are insulated and rubbed, the one order vitreous electricity, and the other resinous electricity.*

Order 1. *Substances which acquire vitreous electricity.*

Pure silver.
Native silver.
Silver coin.
Pure lead.
Pure copper.
Native copper.
Copper coin.
Pure zinc.
Brass.
Native bismuth.
Native amalgam.

Order 2. *Substances which acquire resinous electricity.*

Pure platina.
Native platina.
Palladium.
Pure gold.
Native gold.
Gold coin.

---

[1] That is, they do not require to be insulated or placed upon a substance which does not conduct or carry off electricity, in order to exhibit their electricity.

- Pure nickel.
- Native iron.
- Hammered iron.
- Pure tin.
- Amalgam of tin and mercury.
- Native arsenic.
- Pure antimony.
- Native antimony.
- Tellurium of naygag.
- Antimonial silver.
- Arsenical nickel.
- Arsenical iron.
- Oxidulated iron.
- Metalloidal oxide of manganese.
- Sulphuret of silver.
- Sulphuret of lead.
- Copper pyrites.
- Grey copper.
- Sulphuret of copper.
- Graphite.
- Common sulphuret of iron.
- White sulphuret of iron.
- Magnetic sulphuret of iron.
- Sulphuret of tin.
- Sulphuret of bismuth.
- Sulphuret of manganese.
- Sulphuret of antimony.
- Sulphuret of molybdena.
- Chromate of iron.
- Oxide of iron.
- Jenite.
- Black oxide of cobalt.
- Oxidulated uranium.
- Wolfram.
- Tantalite.
- Yttro-tantalite.
- Black oxide of cerium.

Class IV.—*Containing substances which acquire resinous electricity by friction. The insulating property is limited to the very transparent varieties.*

- Ruby silver.
- Sulphuret of mercury.
- Red copper ore.
- Oligist iron ore.
- Sulphuret of arsenic.
- Titanite.
- Anatase.
- Muriate of mercury.
- Chromate of lead.
- Phosphate of lead.
- Molybdate of lead.
- Green carbonate of copper.[1]
- Blue carbonate of copper.
- Arseniate of copper.
- Dioptase.
- Phosphate of copper.
- Hydrate of copper.
- Sulphate of copper.
- Phosphate of iron.
- Arseniate of iron.
- Sulphate of iron.
- Sulphuret of zinc.
- Red cobalt.
- Green oxide of uranium.
- White oxide of antimony.
- Red oxide of cerium.

As the causes which determine the production of positive or negative electricity by friction are wholly unknown, and require to be carefully investigated, we must warn the philosopher against the implicit adoption of all the preceding determinations. Different results have in many cases been obtained by different observers, and even by the same observer while using the same materials; and we could have greatly enlarged the first of the preceding tables had we inserted the opposite results of different philosophers. There are two points, however, which require to be attended to in such inquiries: 1*st*, There is a tendency to the production of negative electricity in the substance which has the least extent of surface; and, 2*dly*, there is a tendency to the production of an opposite electricity when the surface of the body is even minutely scratched.

Sect. IV.—*On Electrical Conduction.*

Electrical conduction.

It is obvious, from all the phenomena described in the preceding sections, that electricity is communicated from one body to another. The excited glass or wax communicate, as we have seen, their electricity to a pith ball; and the electricity of the machine is conveyed first to the prime conductor, and from that to the bells or other apparatus which have been already described. If we touch an electrified pith ball, or any other electrified body, with a rod of metal of any kind, the electricity of the pith ball will be instantly carried off; but if we touch it with glass or wax it will not be carried off. Hence metals are said to be *conductors*, and glass and wax *non-conductors*, of electricity.

Bodies vary greatly in the degree in which they conduct electricity; and many of them owe their conducting power to the water which they contain. The conducting power of any substance depends on the state of the atmosphere at the time with regard to humidity, and on the intensity of the electricity employed. The following tables of conductors and non-conductors have been collected from different authors. The bodies are placed in the order of their conducting or non-conducting power; but it is probable that this order would be greatly changed if the bodies were all submitted to a new and uniform examination.

List of Conductors.

- All metals.
- Silver.
- Copper.
- Lead.
- Gold.
- Brass.
- Zinc.
- Tin.
- Platina.
- Palladium.
- Iron heated.
- Iron cold.
- Charcoal well burned.
- Plumbago.
- Concentrated acids.
- Powdered charcoal.
- Diluted acids.
- Saline solutions.
- Metallic ores.
- Animal fluids.
- Hot water.
- Sea water.
- Spring water.
- River water.
- Ice above — 13° Fahr.
- Snow.
- Living vegetables.
- Living animals.
- Flame.
- Smoke.
- Steam.
- Soluble salts.
- Rarefied air.
- Vapour of alcohol.
- Vapour of ether.
- Moist earths.
- Anthracite.
- All the substances and minerals in the third class of Haüy's list, as given in Sect. II.
- Powdered glass.
- Flowers of sulphur.
- Resins rendered fluid by heat.
- Glass heated to redness.

List of Non-conductors.

- Shell-lac.
- Amber.
- Resins.
- Sulphur.
- Wax.
- Jet.
- Glass.
- Vitrifications.
- Mica,
- Diamond,
- Transparent gems,
- And all the minerals in Class I. of Haüy's list.
- Raw silk.
- Bleached silk.
- Dyed silk.
- Wool.
- Hair.
- Feathers.
- Dry paper.
- Parchment.
- Leather.
- Air and all dry gases.
- Baked wood.
- Dry vegetable bodies.
- Porcelain,
- Dry marble, and
- Siliceous and argillaceous stones in Class I. of Haüy's list.
- Camphor.
- Caoutchouc.
- Lycopodium.
- Dry chalk.
- Lime.
- Phosphorus.
- Ice below — 13° Fahr.
- Ashes of animal bodies.
- Ashes of vegetable bodies.
- Oils, the heaviest being the best conductors.
- Dry metallic oxides.

Insulato

The most perfect *non-conductors* of electricity are also called *insulators*, from their power of insulating an electrified body, or preventing any of its electricity from escaping along its support. It is to Coulomb that we owe the useful discovery that *shell-lac* is the most perfect of all insulators; and hence it is of great value in electrical inquiries. Coulomb found that the electricity of a pith ball five or six lines in diameter could be completely insulated by a cylinder of sealing-wax or gum-lac about half a line in diameter and eighteen or twenty lines long; that a very fine silk thread, penetrated and covered with melted wax so as to form a cylinder one fourth of a line in diameter, had the same insulating power when its length was five or six inches; and that an equal degree of insulation could not be obtained by a fine thread of glass five or six inches long, or by a hair or a fibre of silk, unless the electricity insulated was very weak, or the air very dry. Coulomb found also that the density of electricity insulated by a fibre of gum-lac was ten times as great as that which could be insulated by a silk fibre of the same length and diameter; and he established the following general law, *that the densities of electricity insulated by different lengths of fine cylindrical fibres, such as those of gum-lac, hair, silk, &c. vary as the square root of the lengths of the fibre.*

---

[1] This salt has often the insulating property, and acquires vitreous electricity by friction.

In examining whether or not positive and negative electricity were conveyed with equal facility by conducting bodies, M. Erman found that there were some bodies which completely obstructed the passage of one kind of electricity, while they afforded a ready passage to the other. As this result, however, was obtained by weak galvanic electricity, the question is still open to examination in reference to ordinary electricity.

Although some bodies are said to be perfect non-conductors, yet this is not strictly true. A strong electrical charge can be made to pass through a thin film of the worst conductor. Dr Ritchie found that electricity permeated thin balls of blown glass; and though in one case he found that a small invisible aperture had been made in the glass, yet in other experiments he could not by any known method detect the smallest perforation.

It has been long known that imperfect conductors have their conducting power increased by heat; gases, charcoal, glass, ice, and resins when melted, are proofs of this. Dr Ritchie,[1] on the authority of some accurate experiments, is of opinion, that if the body be naturally a pretty good conductor, the ratio of its conducting power will not be so much increased by heat as in the case of a less perfect conductor. Marianini found this to be true with fluid conductors, and Dr Ritchie thinks that it is universally true.

It appears from some recent experiments made by Professor Delarive of Geneva, that the degree of conductibility of bodies for electricity *depends on the quantity of electricity which traverses them.* Hence it follows, that, of two conducting bodies, that which is the most perfect for an electric current of a given intensity, may be the worst conductor for either a stronger or a weaker current. The conducting powers of bodies, therefore, ought to be re-examined in reference to electric currents of different intensities; and when such experiments are made with accuracy, we may expect that they will lead to great improvements in our electrical apparatus.

Much light has been recently thrown on the conducting power of bodies by the researches of Dr Faraday, of which we have already given a general account in our history of electricity. He found that a great number of solid bodies which were incapable of conducting electricity of low tension, acquired by liquefaction or fusion the power of conducting it in a very high degree. The following is a list of the bodies which possessed this property:

Water.

Oxides. Potassa, protoxide of lead, glass of antimony, protoxide of antimony, oxide of bismuth.

Chlorides of potassium, sodium, barium, strontium, magnesium, manganese, zinc, copper (proto-), lead, tin (proto-), antimony, silver.

Iodides of potassium, zinc, and lead; protiodide of tin, periodide of mercury, fluoride of potassium, cyanide of potassium, sulpho-cyanide of potassium.

Salts. Chlorate of potassa; nitrates of potassa, soda, baryta, strontia, lead, copper, and silver; sulphates of soda and lead; proto-sulphate of mercury; phosphates of potassa, soda, lead, copper, phosphoric glass, or acid phosphate of lime; carbonates of potassa and soda, mingled and separate; borax, borate of lead, perborate of tin; chromate of potassa, bichromate of potassa; chromate of lead; acetate of potassa.

Sulphurets. Sulphuret of antimony, sulphuret of potassium made by reducing sulphate of potassa by hydrogen, ordinary sulphate of potassa.

Silicated potassa; chameleon mineral.

In those substances which soften before they liquefy, Dr Faraday found it highly interesting to watch the increase of conducting power as they approached to perfect fluidity. When borate of lead, for example, is heated by the lamp upon glass, it becomes as soft as treacle, without gaining the power of conduction; and it was only when brought to a fair red heat by the blowpipe that it conducted. When it was quite liquid, it conducted with extreme facility.

The following bodies were found by Dr Faraday to acquire no conducting power when they assumed the liquid state.

Sulphur.
Phosphorus.
Iodide of sulphur.
Periodide of tin.
Orpiment.
Realgar.
Glacial acetic acid.
Mixed margaric and oleic acids.
Artificial camphor.
Caffeine.
Sugar.
Adipocire.
Stearine of cocoa-nut oil.
Spermaceti.
Camphor.
Naphthaline.
Resin.
Gum sandarach
Shell-lac.
Perchloride of tin.
Chloride of arsenic.
Hydrated do.

Boracic acid and green bottle glass raised to the highest heat by an oxyhydrogen flame acquired no conducting power. Flint glass conducted a little when so heated.

When a solid becomes fluid it loses almost wholly its power of conducting heat, and gains in a high degree that of conducting electricity, and *vice versa;* and hence Dr Faraday concludes that there is a natural dependence between the two classes of facts.

Dr Faraday concludes his very interesting researches on this subject with the following summary of conditions of conduction in bodies, which, though they apply chiefly to Voltaic electricity, are yet true within certain limits for ordinary electricity.

Conditions of electrical conduction.

1. All bodies conduct electricity in the same manner from metals to lac and gases, but in different degrees.

2. Conducting power is in some bodies powerfully increased by heat, and in others diminished, yet without our perceiving any accompanying essential electrical difference, either in the bodies or in the changes occasioned by the electricity conducted.

---

[1] *Philosophical Transactions*, 1828, p. 376.

3. A number of bodies insulating electricity of low intensity when solid, conduct it very freely when fluid, and are then decomposed by it.

4. There are many fluid bodies which do not sensibly conduct electricity of this low intensity; there are some which conduct it and are not decomposed, nor is fluidity essential to decomposition.

5. There is but one body yet discovered (periodide of mercury) which, insulating a Voltaic current when solid, and conducting it when fluid, is not decomposed in the latter case.

6. There is no strict electrical distinction of conductors which can as yet be drawn between bodies supposed to be elementary and those known to be compounds.

The experiments of Dr Faraday with ice, in which it appeared that electricity of exalted intensity passed through it, while it completely stopped Voltaic electricity, confirms the observations of M. Delarive on the relation between the conducting power and the quantity of electricity which traverses the conductor; and the phenomena seem to indicate that the electric fluid or matter may consist, like solar light, of different parts possessing different powers of conductibility and other properties, which may facilitate or obstruct their passage through solid, fluid, or gaseous bodies. An electric current, composed of different currents, may have some of its component currents entirely stopped by some bodies, while other currents are transmitted with the greatest facility, in the same way as certain rays both of light and heat are entirely absorbed by coloured bodies, while other rays are copiously transmitted. Non-conductors, like black bodies, stop every electrical current. Perfect conductors, like colourless transparent bodies, may transmit every electrical current, or absorb a small portion of all of them in an equal degree; while there may be imperfect conductors, which, like coloured bodies, stop some currents and transmit others. If this should prove correct, two bodies which, when used separately, conduct electricity, would be insulators when joined so as to transmit the electricity in succession, in the same manner as two transparent coloured bodies which separately transmit light copiously, are opaque when combined, the light which each transmits being absorbed by the other.

Distance to which electricity has been conducted.

We have already seen that electricity was conveyed through a distance of four miles. On the ground that these experiments were made imperfectly, and that an electric charge will prefer a short passage through air to a passage of twenty or thirty feet through thin wire, Mr Singers has expressed his conviction that the results of the experiments referred to are incorrect. We are unable, we confess, to appreciate the reasons on which this opinion is founded; but, even if they have any force, the original fact has been more than confirmed by Mr F. Ronalds, who erected at Hammersmith an electrical telegraph, on which the inflections of the wire composed *one continuous length of more than* EIGHT *miles.* "When a Canton's pith ball electrometer was connected with each extremity of this wire, and it was charged by a Leyden jar, both electrometers appeared to diverge suddenly at the same moment; and when the wire was discharged by being touched with the hand, both electrometers appeared to collapse as suddenly. When any person took a shock through the whole length of wire, and the shock was compelled to pass also through two insulated inflammable air pistols, one connected with each extremity of the wire, *the shock and the explosion seemed to occur quite simultaneously.* But when the shock was compelled to pass through the gas pistols, and any one closed his eyes, it was *impossible* to distinguish more than one explosion, although both pistols were discharged. When people did not look at the pistols, and when I sometimes charged only one highly, and sometimes both lowly, they could never guess, except by mere chance, whether one or both were fired. *Thus, then, three of the senses, namely, sight, feeling, and hearing, seemed to receive absolute conviction of the instantaneous transmission of electrical signs through my pistols, my* EIGHT *miles of wire, and my own proper person.*"[1]

SECT. V.—*On the Electric Spark.*

Electr. spark.

Since the discovery of electric light by Otto Guericke and Dr Wall, the subject has attracted the particular attention of philosophers. In exciting a glass tube, or in working an electrical machine in the dark, sparks and streams of light are distinctly visible; but the phenomenon is best seen when the knuckle or a brass ball is brought near to an electrified conductor. A bright light, called the *electric* spark, passes from the conductor to the knuckle or ball, and exhibits a great variety of phenomena, varying with the nature and intensity of the electricity, and with the form, magnitude, distance, and nature of the bodies between which it passes.

Form the sp

Pl. CC

Fig. 6, 8.

Exp. 1. Having screwed into the prime conductor a brass ball about two inches in diameter, and projecting about three inches, electrify the conductor positively, and hold another ball near the first. Long ramified zigzag sparks will pass between the two balls, as shown in fig. 6, where *pos.* is the *positively* electrified ball, and *nat.* the one held in the hand in a natural state of electricity. If the ball on the conductor is very small, the spark will become a faint divided brush of light. If the ball on the conductor is electrified negatively, the spark will be as shown in fig. 7, clear, straight, and more luminous. If one of the balls is *positively*, and the other *negatively* electrified, the forms shown in fig. 6 and 7 will be combined, as in fig. 8. When, in this last experiment, the distance of the balls is not too great, the positive zigzag spark will strike the negative straight spark about one third of the length of the latter from its point, the other two thirds becoming very luminous. Sometimes the positive spark strikes the negative ball at a distance from the negative spark.

Fig. 9

Exp. 2. If two conductors PM, fig. 9, three fourths of an inch in diameter, and having spherical ends, are placed parallel to each other, at the distance of two inches, so as to have their ends pointing in different directions six or eight inches asunder; then, if P is positively electrified, its spark will strike the other conductor M in its natural state, as in fig. 9. If M is electrified negatively, and P connected with the earth, the conductor M will send the negative spark to P, as in fig. 10; and if the conductors have opposite electricities, the positive spark will appear at one end, and the negative at the other, as shown in fig. 11.

Fig. 1

Exp. 3. Upon the brass stem *bc*, fig. 12, having a fine point at *c*, place a brass ball A, about three inches radius, so that the point *c* can be protruded to any distance beyond the ball, or be drawn within it, as shown in the figure. In this last state the point produces no effect, and the zigzag spark appears between the balls.

In proportion, however, as the point is protruded, its transmitting power is increased, and it may be made to have the same effect as any ball, from the smallest size to one three inches radius. When the point projects to a particular distance, it acts as if no ball were present.

---

[1] *Description of an Electrical Telegraph, &c.* p. 4. Lond. 1823.

Phome- n nd ws.

Exp. 4. Hold an insulated sheet of paper at a small distance from a *positively* electrified conductor, and a beautiful star with distinct radiations will be thrown upon the paper. If the conductor is *negatively* electrical, a cone of rays, with its base on the paper and its apex on the conductor, will replace the star.

Exp. 5. If the point of a needle is presented to a positively electrified conductor in the dark, the point will be illuminated with a star; but if the conductor is *negative*, the needle will exhibit a pencil or brush of light.

The following experiment illustrates the effect of distance on the spark.

In ence of tance on e sp

Exp. 6. Fix a sharp-pointed wire to the end of the prime conductor, and having electrified it positively, hold an uninsulated ball of metal very near the metallic point; a succession of small and *brilliantly white* sparks will pass between them. The white colour will tend to red as the distance of the ball and the point is increased, and at a certain distance the sharp explosions will cease, and a feeble violet light will diverge from the extremity of the point, covering with its base the nearest half of the sphere.

In ence of m on th park.

The influence of the form of the body upon the spark which it gives is considerable. Professor Hildebrand of Erlang found that an obtuse cone with an angle of 52° gave a much more luminous spark than one with an angle of 36°, and he found that the parabolic rounding of the summit, or slight inequalities of surface, are particularly advantageous in the production of a strong light. The influence of points on the spark has been already described.

In ence of b- st e on th park.

The nature of the body by which the spark is taken exercises also an influence upon its magnitude and its colour. Professor Hildebrand made some interesting experiments on this subject. The pieces of metal had a conical form, and of the same shape and size. When they were fixed in the same manner at the end of an insulated conductor, the sparks which they yielded differed much in extent. The following table exhibits the results of these experiments, the metals at the head giving the greatest sparks.

Regulus of antimony.
Gold.
Silver.
Brass.
Sulphuret of copper.
Tin.
Zinc.
Iron.
Lead.
Steel.
Tempered steel.

When the spark is *white* by taking it with a metallic body, it will under the same circumstances be *violet* if taken with the finger. If the spark is taken with ice or water, or a green plant, its light will be red; and if it is taken with an imperfect conductor, such as wood, the light will be emitted in faint red streams.

I ence o e me- d on t park;

P CX. F 13.

The medium through which the spark is transmitted exercises also a remarkable influence on its colour and form. A spark capable of passing through only half an inch in common air, will pervade six inches of the Torricellian vacuum. The apparatus used by Sir H. Davy for examining the influence of a vacuum, &c. is shown in fig. 13, where ABC is a bent glass tube, A the wire for communicating electricity, D the surface of quicksilver or fused tin for producing a vacuum, D the tube to be exhausted by the stop-cock C, after being filled by means of the same stop-cock when necessary with hydrogen, and EF the moveable tube connected with the air-pump. Sir H. Davy found, that in all cases when the mercurial vacuum was perfect, it was permeable to electricity, and rendered luminous either by the common spark or the charge of a Leyden jar. The intensity of these phenomena varied with the temperature. When the tube ABC was very hot, the electric light appeared on the vapour of the mercurial vacuum of a bright green colour, and of great density. As the temperature diminished it lost its vividness. At 20° below zero of Fahrenheit it was perceptible only in considerable darkness. When the minutest quantity of rare air was introduced into the mercurial vacuum, the colour of the electric light changed from *green* to *sea green*, and by increasing the quantity, to *blue* and *purple*. At a low temperature the vacuum became a much better conductor. A vacuum above fused tin exhibited nearly the same phenomena. At temperatures below zero the light was yellow, and of the palest phosphorescent kind, just visible in great darkness, and not increased by heat. When the vacuum was formed by pure olive oil, and by chloride of antimony, the electric light through the vapour of the chloride was more brilliant than that through the vapour of the oil; and in the last it was more brilliant than in the vapour of mercury at common temperatures. The light was of a *pure white* with the chloride, and of a *red* inclining to *purple* in the oil.

o f tem- P ture.

Phenomena and Laws.

Colours of the spark.

Upon rarefying the air five hundred times in a glass vessel a foot long and eight inches in diameter, Mr Smeaton made the vessel revolve rapidly on a lathe, at the same time exciting it with the palm of his hand. A large quantity of lambent flame appeared under his hand, *variegated with all the colours of the rainbow.* Though the light was steady, every part of it was continually changing colours.

In carbonic acid gas the light of the spark is white and brilliant, and in hydrogen gas it is red and faint. When the sparks are made to pass through balls of wood or ivory they are of a *crimson* colour. They are *yellow* when taken over powdered charcoal, *green* over the surface of silvered leather, and purple from imperfect conductors.

Experiments on electrical light.

The following experiments on the spark and electrical light are both instructive and entertaining.

Exp. 1. Cover a metallic wire with silk, and form it into a close flat spiral of not more than twenty-four revolutions, with the different coils in contact. When a considerable electric charge (of about two square feet of coated surface) is passed through it, a vivid light resembling that of an artificial fire-work will be seen, even in daylight, originating in the centre of the spires. M. Nobili considers this light as electro-magnetic light, on account of its relation to the magnetic state of the spiral, and as similar to the aurora borealis.

Exp. 2. Take a bound book covered with rich gilding, and, holding it in one hand, bring it near the prime conductor. The spark will immediately shoot along the gilding in sparks or streams of green light, and will exhibit the pattern in the dark, and enable the observers to read the gilt title of the book.

Pl. CCX. Fig. 14.

Exp. 3. In the preceding experiment the letters themselves were covered with a metallic film; but if we construct an apparatus like that in fig. 14, on which the word LIGHT is left blank in a continuous line of narrow tinfoil pasted upon glass, and forming seven parallel lines, and apply the ball B to an electrified prime conductor, the word LIGHT will be seen in the dark in luminous letters formed by the electric spark passing from one piece of tinfoil to the opposite one. Figures of all kinds may in a similar manner be delineated electrically.

Luminous spirals. Fig. 15.

Exp. 4. Another beautiful experiment, called the *luminous spiral tubes*, is shown in fig. 15, where a number of round pieces of tinfoil are pasted spirally upon four glass tubes *a*, *b*, *c*, *d*, fixed on a board round a central rod of glass AB, supporting horizontally a wire *mn* with brass balls, and capable of turning round the pivot A. Electrify by sparks the wire at A, and pushing the wire *mn* gently round, the ball at the top of each tube will receive electricity from *a* or *b*, and a brilliant line of light will appear to surround each ball in succession, in consequence of the spark appearing between each of the small circles of tinfoil.

Luminous jar. Fig. 16.

Exp. 5. The *luminous jar* shown in fig. 16 is a still more beautiful experiment. In one which is now before us, fifty-five squares of tinfoil an inch square, and each perforated with a hole four tenths of an inch in diameter, are pasted in five rows on the outside and inside of a glass jar AB, fig. 16, about five inches in diameter and eleven inches high. The diagonals of the square pieces are placed horizontal and vertical, and their points or angles are separated by about one twelfth of an inch. The rows of the tinfoil squares are similarly placed on the inside of the jar, with this difference only, that their horizontal points nearly touch one another at the centres of the circular holes of the outer squares. The brass ball A communicates with the inside squares by a wire, and when it is charged by the prime conductor, a hundred and ten sparks will be seen at once in a horizontal, and a hundred and ten in a vertical direction, when the jar is discharged.

Exp. 6. Take a glass cylinder three inches wide and three feet long, so fitted up that a brass plate may be let down from the top of the cylinder, so as to stand at any distance from another brass plate fixed at the bottom of the cylinder. When the cylinder is exhausted of air in the usual manner, and the upper plate communicates with the prime conductor, and the lower one with the ground, a brilliant sheet of light will pass from the upper to the lower plate. If the distance of the plates is ten inches, and if the charge of a Leyden jar is made to pass from the one to the other, a continuous body of the most brilliant fire will pass between them.

Sect. VI.—*On the Nature and Origin of Electrical Light.*

Nature of electrical light. Wollaston.

Dr Wollaston seems to have been the first person who made any accurate examination of electric light, and the following is all that he has published as the result of his experiments. "When the object viewed is a *blue* line of electric light, I have found the spectrum to be also separated into several images; but the phenomena are somewhat different from the preceding (viz. the spectrum of the blue portion of the flame of a candle). It is, however, needless to describe minutely appearances which vary according to the brilliancy of the light, and which I cannot undertake to explain."[1] M. Biot, in speaking of electric light, remarks, "that if we look through a prism at the sparks which pass between two conductors oppositely electrified, we shall find all the colours which compose common light."[2]

Biot.

Fraunhofer.

M. Fraunhofer examined the electric spark in a more philosophical manner. In order to obtain a continuous line of electrical light, he brought to within half an inch of each other two conductors, and united them by a very fine glass thread. One of the two was connected with an electrical machine, and the other communicated with the ground. In this manner the light appeared to pass continuously along the fibre of glass, which consequently formed a fine and brilliant line of light. When this luminous line was expanded by refraction, Fraunhofer saw that, in relation to the lines of its spectrum, electric light was very different both from the light of the sun and from that of a lamp. In this spectrum he met with several lines partly very clear, and one of which in the green space seemed very brilliant compared with other parts of the spectrum. He saw in the orange another line not quite so bright, which appeared to be of the same colour as that in lamp-light spectra; but in measuring its angle of refraction he found that its light was much more strongly refracted, and nearly as much as the yellow rays of lamp light. In the red rays towards the extremity of the spectrum, he saw a line of very little brightness, and yet its light had the same degree of refrangibility as the clear line of lamp light. In the rest of the spectrum he saw other four lines sufficiently bright.[3] In a subsequent paper read at Munich in 1823, Fraunhofer observes, that by means of the large electrical machine in the cabinet of the Academy of Munich, he obtained a spectrum of electric light, in which he recognised a great number of light lines, and that he had determined the relative places of the lightest lines, and the ratios of their intensities. What these positions and ratios were we have no means of knowing, as we believe that this distinguished philosopher has not given them to the public.

Brews

The nature of electric light has been more recently examined by Sir David Brewster. He had long ago shown that the light of electricity was refracted singly and doubly, and polarised exactly like all other light; but his recent observations were made, like those of Fraunhofer, on the dark and luminous lines which appear in the spectrum formed from it by a prism. Fraunhofer examined the electric light produced in the manner he has described. In this *species* of electric light Sir David Brewster observed the lines described by Fraunhofer, and also its remarkable difference from that of the sun and a lamp in relation to the fixed lines of the spectrum. This difference he found to arise from the fact that certain *colorific* rays which exist in solar light do not exist in electrical light, though, in some parts of the spectrum, other rays of equal refrangibility are visible. The extreme red space, for example, is wanting, and, generally speaking, much of the red and yellow light. Hence the light of the electric spectrum is *green* at a line or point of a given refrangibility, where it is *yellow* in the solar spectrum. These facts confirm in a remarkable manner the discovery that the spectrum consists of three superimposed spectra of blue, yellow, and red light, of equal lengths,[4] and receive from that discovery a complete explanation.

Sir David Brewster examined electric light of various colours, and produced under different circumstances, and he found it to differ in its composition in a very remarkable manner, each variety of electric light varying in the number, intensity, and position of its bright and defective rays. One species of electric light is as different from another as the coloured lights produced in the flame of alcohol in which different saline substances have been dissolved. It would require almost the lifetime of an individual to examine and make drawings of this class of phenomena while the light passes from a violet, through blue, green, yellow, and red, up to white light. The bright lines which occur in the green space have a most singular appearance. They shine, in reference to the rest, with the metallic brilliancy of silver; and each successive spark, obtained under nearly the same circumstances, will often present to us these lines under different intensities and characters. In another part of this work we may be able to communicate the results of these experiments, which are now going on. In the mean time they furnish us with a most important fact relative to the theories which have been maintained concerning the cause or origin of electric light.

[4] *Edinr. Trans.* vol. xii.

It has been the general opinion of philosophers that the electric spark was the electric fluid itself, or, as Biot expresses it, " a modification of electricity itself, which had the faculty of becoming light at a certain degree of accumulation." This eminent writer, however, considered this opinion as erroneous, and has devoted a whole chapter to prove that electric light has the same origin as the light disengaged from air by mechanical pressure, " *and that it is purely the effect of the compression produced on the air by the explosion of electricity.*" In order to establish this theory, M. Biot has stated, on the authority of several experiments, " that the intensity of electric light depends always on the ratio which exists between the quantity of electricity transmitted and the resistance of the medium; and he has shown, by an experiment with Kinnersley's air thermometer, " that at each spark the air of the cylinder, driven by the repulsive force, presses on the surface of mercury, which rises suddenly in the small tube, and falls back again immediately after the explosion." " This indication," he adds, " proves the separation produced between the particles of the mass of air where the electricity passes; and from what we know of its extreme velocity, it is certain that the particles exposed immediately to its shock ought in the first moment to sustain individually all the effect of the compression. They ought, then, from this cause alone to disengage light as when they are subjected to any other mechanical pressure. *Thus one part at least* of the electric light is *necessarily* due to this cause; and this being the case, there is no experiment which can lead us to conjecture that it is not all due to this cause."[1]

These arguments, whatever may be their weight, carry no conviction to our mind. When we possess two series of accurate experiments, by which it is proved that light produced by mechanical pressure in air and gases, of different bulks, and of different degrees of temperature, rarefaction, and condensation, has the same colour, the same composition, and the same general character, as the light produced by electricity in passing through air and gases under the very same circumstances, we shall regard this theory as deserving of consideration.

M. Biot, anticipating the objection that electrical light is produced in the best vacuum, replies, that a vacuum such as we can produce is filled with vapours and gas, and that the barometric one is filled with mercurial vapour. Still, however, the light produced is not produced by air, and it should be shown that mechanical pressure is capable of eliciting light in such a vacuum; at all events, the light ought to bear some proportion to the degree of rarefaction, whereas Sir H. Davy obtained a bright light in the best vacuum with mercury, and the same light in the best vacuum with melted tin.

Anticipating another objection from the fact that the electric spark, when intense, passes through water, M. Biot gives a double reply, 1*st*, that the water itself is probably compressible, and therefore, we presume, gives out light during its compression; and, 2*dly*, that water always contains in combination a certain quantity of air, which may also contribute to the result. It would be desirable, therefore, to ascertain if water, and water with much air, give out light by mechanical compression.

In explaining the fact that electrical light is *violet* when the electricity is *feeble*, and of a *brilliant whiteness* when it is produced by a violent discharge, M. Biot remarks that " this variation of tints discloses still further the origin of the light; for we observe it in substances which burn according as the combustion is slow or rapid; that is to say, according as the oxygen of the air which this combustion absorbs is more or less rapidly condensed. The light which sulphur disengages when it begins to inflame is as *violet* as that of feeble electricity, but that of sulphur in vigorous combustion is *white*." The views upon which this argument is founded are themselves hypothetical. It is by no means made out that the colour passes from *violet* to *white* as the intensity of combustion increases; and, in the very case of *sulphur* referred to by M. Biot, Sir John Herschel has proved, that when it is inflamed in a white hot crucible, it gives out neither *blue*, *green*, nor *red* rays, but solely *homogeneous yellow light*, of a very definite refrangibility, and which contains almost none of the elements of *white* light.

Sir H. Davy's theory.

A more philosophical view of the probable origin of electrical light has been hinted at by Sir Humphry Davy, in his paper of 1822, already quoted. " The circumstance," says he, " that the intensity of the electrical light in the mercurial vacuum diminishes as it is cooled to a certain point, when the vapour must be of infinitely small density, and is then stationary, seems strongly opposed to the idea that it (electrical light) is owing to any permanent vapour emitted constantly by the mercury. The results with tin must be regarded as more equivocal; because, as this substance cannot be boiled in vacuo, it may be always suspected to have emitted a small quantity of the rare air or gas to which it has been exposed; yet, supposing this circumstance, such gas must be at least as highly expanded as the vapour from cooled mercury, and can hardly be supposed capable of affording the *dense* light which the passage of the charged Leyden phial through the vacuum produces.

" When the intense heat produced by electricity is considered, and the strong attractive powers of differently electrified surfaces, and the rapidity of the changes of state, it does not seem at all improbable that the superficial particles of bodies, which, when detached by the repulsive power of heat, form vapour, may be likewise detached by electrical powers, and that they may produce luminous appearances in a vacuum, free from all other matter, by the annihilation of their opposite electrical state.

" In common cases of electrical action, the quantity of the heat generated by the annihilation of the different states depends upon the nature of the matter on which it acts; and in cases where electrical sparks are taken in fluids, vapour or gas is always generated; and in elastic fluids, the intensity of the light is always greater the denser the medium."[2]

Discoveries of Dr Fusinieri.

About the same time that Sir H. Davy was occupied with these researches, Dr Fusinieri was engaged in those beautiful experiments on electric light which have added so greatly to our knowledge of its nature and origin. The results of these experiments, which seem to have been commenced in 1821, were published in successive years. In 1825 there appeared, in the Journal of Pavia, a most interesting communication, of which the following is a brief abstract, relative to the transport of ponderable matter in the electrical discharges of ordinary machines; and, in 1831, another of equal importance on the transport of ponderable substances by lightning.

Dr Fusinieri has proved that the electric spark which issues from a *brass* conductor, and traverses air, contains brass in the state of fusion, and incandescent molecules of zinc.

When the spark issues from a globe of *silver*, it contains in its passage through air silver in fusion, and incandescent molecules of the same metal.

---

[1] *Traité de Physique*, tom. ii. p. 463.

[2] *Phil. Trans.* 1822, p. 72-73.

If the spark which issues from silver traverses a plate of copper, the silver which it contains passes also through the copper in perforating it, and in traversing even a space of several centimeters, if the passage is oblique from the one surface to the other.

In this passage a portion of the transported silver is detained in the aperture which is made in the copper, and another portion follows the current, and penetrates the ball which receives the electric spark.

When the electric spark issues from a ball of *gold*, and passes into air, it contains gold in a state of fusion, and also incandescent molecules of gold.

If the spark from *gold* traverses a plate of *silver*, the gold contained in the spark traverses the plate in piercing it; and in traversing a space of several centimeters in the silver, if the direction of the passage is oblique, a part of the transported gold remains in the silver, and spreads itself over the two surfaces of the plate, and another part accompanies the electric current, and penetrates the ball which receives the spark. The gold spread over the polished surface of the silver appears in the form of a thin circular stratum upon the surface where it enters, and upon the surface where it leaves the plate. The very same result takes place if the spark passes from brass to silver.

These strata or metallic spots are so exceedingly thin, that after a certain time they are volatilized and disappear.

Dr Fusinieri also found that in each passage of the spark there was an opposite and reciprocal transport of the two metals. In a spark from silver to copper, part of the copper is transported to the silver, as well as the silver to the copper; and the same reciprocal transfer takes place in a spark from gold to silver.

Accompanying this reciprocal transport, there are two strong and opposite percussions produced by the transported metal, one at the point where it is detached, the other at the point where it enters the other metal. These two percussions show themselves, by two opposite cavities which contain the same metal, in such a state as to indicate fusion. Here the transported metal exerts two pressures in opposite directions.

In passing from one metal to another, the electric current leaves the first metal in the second, and takes with it a small quantity of the second.

The electric spark which issues from a metal into air contains a group of molecules, the most central of which are in a state of simple fusion, and the exterior ones are in a state of greater or less combustion, from their contact with oxygen, according as the metal is more or less oxidable; and the matter thus contained in the spark is endowed with a force of spontaneous expansion.[1]

From these highly interesting facts Dr Fusinieri draws the following important conclusions respecting the nature and origin of electric light. 1. The electric spark is not formed by a pure fluid, or by any imponderable fluid. 2. The heat and light of the spark proceed from the ignition and combustion of the particles of ponderable matter. 3. The presence of air produces on the spark two distinct effects, the one to hinder its free expansion in space, the other, by supplying oxygen, to promote the combustion of the exterior molecules of the group, while the central molecules are luminous from ignition and fusion alone. 4. In gases without oxygen, the material molecules which compose the spark ought to be simply in a state of incandescence and fusion, without any combustion of the exterior particles of the group, in the same manner as this takes place for the central parts of the spark in common air. 5. In gases deprived of oxygen, as well as in a vacuum, the molecules which compose the spark ought to be incandescent; that is, in a state which fits them to emit light and heat; a phenomenon of the same kind as those inflammations which chemical experiments prove to take place even without the aid of oxygen, in so great a number of other combinations, or even without there being any new combinations, by the sole effect of division of parts.

In a later memoir on the transport of ponderable substances by lightning, published in the *Ann. delle Scienze del Regno Lomb. Veneto* for 1831, Dr Fusinieri has shown, by a series of laborious and beautiful observations, that lightning leaves in houses and on trees traces of ferruginous and sulphureous substances which it contains; and he infers that iron exists in the clouds, having been attracted[2] from the earth, and principally from mountains, where the mines are more abundant, and where storms generally begin to form. Hence, as Dr Fusinieri supposes, we may connect this fact with meteoric stones, and with the magnetic currents which surround the globe. In our chapter on atmospheric electricity, we may probably find space for a further notice of Dr Fusinieri's researches.

That the electric spark *is a flame*, and consists, like all other flames, of incandescent molecules in a state of minute subdivision, will, we think, be now admitted by every philosopher; and it cannot fail to be observed how singularly this result harmonizes with the varied composition of electric light of different kinds and colours, as ascertained by Sir David Brewster by means of prismatic analysis;—and from the comparison which he is making between the composition of electric light consisting of different ponderable substances, and that of flames in which the same ponderable substances exist in a state of incandescence, there is reason to expect that these two widely separated classes of phenomena may be strictly identified.

SECT. VII.—*On the Law of Electrical Attraction and Repulsion, and the Attraction of Spheres and Planes.*

Law electr attrac and r sion.

It is obvious, from the simplest experiments, that the force of electrical attraction and repulsion diminishes with the distance. In the theories of Æpinus and Cavendish nothing more than this simple fact has been assumed. Newton had supposed that the forces of electricity and magnetism decreased with the cube, or some higher power, of the distance. Lord Stanhope inferred, from reasonings not very conclusive, that the law was the same as that of gravity; and Dr Robison, so early as 1769, ascertained, from more than a hundred experiments, that the repulsive force diminished according to a power of the distance whose exponent was 2·06, or very nearly as the square of the distance.

Coul torsic lance

Pl. C Fig.

The accurate determination, however, of the law of electrical attraction and repulsion was left to Coulomb. The apparatus which he employed for this purpose, and which is known by the name of the *torsion balance*, is represented in Plate CCXI. fig. 1, where ABCD is a glass cylinder, which is covered with a plate of glass AB thirteen inches in diameter. This plate is perforated with two holes *e* and *a*, the former being intended to receive a tube of glass *e*G two feet high, carrying on its upper end a torsion micrometer, consisting of a graduated circle MN, p ome- i and ws.

---

[1] Dr Fusinieri likewise found that the electric spark obtained between the two poles of the Voltaic pile, terminated either by metals or charcoal, contains also particles of these substances extremely divided, and in a state of combustion.

[2] The iron may be carried off by the lightning which issues from the ground in cases where the clouds are negatively electrified.

an index M, and a pair of pincers, opened and shut by a ring, for holding a slender silver wire GH, whose lower end H is also grasped by a similar pair of pincers made of copper, and about a line in diameter. Through a hole in these copper pincers there passes a horizontal needle *cd*. This needle consists of a silk thread or a straw covered with sealing-wax, but the end of it, at *d*, about eighteen lines long, is a cylinder of gum-lac. It is terminated at *c* by a ball of the pith of elder about two or three lines in diameter, and at *d* by a vertical plane of paper covered with turpentine. A circular band of paper EF, divided into 360°, is pasted round the cylinder on a level with the needle, and at the hole *a* there is introduced a small cylinder *ab*, the lower end of which, made of gum-lac, carries another ball *b* of the pith of elder. The instrument is adjusted when a line passing through the centre of the silver wire GH at P passes also through the centres of the balls *b* and *c*, and points to the zero of the graduated circle EF.

L of the re lsive fo. F 2.

Having fixed a brass pin BC, fig. 2, with a large head B, into a handle of sealing-wax AC, and having electrified the ball B, Coulomb communicated electricity to the balls *b*, *c*. They accordingly repelled each other, and the needle *cd* turned round through a certain arch. By turning, however, the micrometer button in the direction NP, he twisted the wire GH, and caused it to return to its first position, and point to the zero of the scale. When this is done, the force of torsion has been made to balance the repulsive force of the two balls *b*, *c*; so that, by comparing the forces of torsion which balanced the repulsive forces at different distances of the balls, he obtained measures of the repulsive force at these distances. When the distances were 36°, 18°, and 8½°, he found the angle of torsion, or the force of torsion, which is proportional to the angle, to be 36°, 144°, and 575½°; that is, at *half* the distance the force is *four* times greater, and at a *fourth* of the distance the force is nearly *eight* times as great. Hence he concluded that *the repulsive force of two small globes charged either with positive or negative electricity is inversely as the squares of the distances of the centres of the globes.*

I of t attrac- t force.

In applying the same method to determine the law of the attractive force which takes place between two oppositely electrified bodies, M. Coulomb met with a difficulty, arising from the attractive force increasing in a greater ratio than the force of torsion. From this cause it was difficult to prevent the balls from coming into contact, and a delay was created, during which part of the electricity had escaped. By providing against this difficulty, he obtained results which led to the conclusion *that the attractive force of two small globes, one electrified positively and the other negatively, was in the inverse ratio of the squares of the distances of their centres.*

. 3.

In order, however, to confirm this result by an entirely different method, he employed the apparatus shown in fig. 3, where BC is a vertical stand of wood, carrying a horizontal arm of wood AB, divided into inches, upon which there slides another piece of wood ED, to which is suspended, by a fibre of silk *fe*, a horizontal needle of gum-lac *cd*, fifteen lines long, carrying at one end, and perpendicular to the needle, a circle of gilt paper *d*, seven lines in diameter, and at the other end a ball *c* of gum-lac. A globe of copper a foot in diameter, or a globe of paper covered with tinfoil, resting on four insulating cylinders of glass, coated with sealing-wax, is then placed upon a stand, so that it can be raised or depressed, and fixed in any position, so that its horizontal diameter passes through *dc*.

This apparatus is adjusted by placing the globe so that, when the moveable piece E is at *zero* of the scale on BA, the centre of the circle *d* may just touch the globe. When this is done, place the piece E at three inches on the scale, so that the distance of *d* from the globe will be three inches, and then the distance of *d* from the centre of the globe will be nine inches. Let the globe be now electrified by the spark of a Leyden jar; then, if a conductor is made to touch the plate *d*, the globe will communicate to it the opposite electricity upon removing the conductor, and the globe and the plate will attract one another. Cause the needle *cd* to oscillate through an arch of about 20° or 30° from the line where the force of torsion is nothing, and observe the time in which a given number of oscillations, suppose fifteen, is performed. Repeat the very same experiment when the piece E is placed at twelve and eighteen inches on the scale; that is, when the distances of the centres of the attracting bodies are eighteen and twenty-four inches. In doing this, Coulomb obtained the following results:

Distances of centres.	Number of oscillations.	Time in which they were performed.
9	15	20
18	15	40
24	15	60

As the oscillations in the preceding experiments are produced by the attraction of the globe and plate *d*, in the same manner as the oscillations of a pendulum are produced by the force of gravity; then, since the time in which a given number of oscillations is performed is inversely as the square root of the attractive force, and if we assume that the attractive force is inversely as the squares of the distances, or 9, 18, 24, or 3, 6, 8, then it will follow that the time of oscillation is proportional to these distances. These times will consequently be 20″, 41″, and 54″, if the attractive force is inversely as the square of the distance; but by experiment the times were 20″, 40″, and 60″. The difference is therefore almost nothing at 18 inches of distance, but it is nearly $\frac{1}{10}$th at 24 inches. Coulomb has applied a correction to the number 54″, in consequence of the loss of electricity by the two bodies during the four minutes which the experiment occupied. He found by experiment that the action was diminished $\frac{1}{40}$th of the whole per minute, and consequently $\frac{1}{10}$th of the whole in four minutes. Hence, $\sqrt{10} : \sqrt{9} = 60'' : 57''$, a result which now differs only $\frac{1}{20}$th from 60″, the time determined by experiment. Hence it follows, that by both methods of observation, the law of action is the same for attractive as it is for repulsive forces.

We are not aware that these experiments of Coulomb have been repeated and confirmed by other philosophers. Experiments with the torsion balance and contact plane are very difficult and precarious, and it is almost impossible to estimate with accuracy the loss of electricity in the two charged conductors during the performance of the experiment.

Experiments of Mr Snow Harris.

Under these circumstances, Mr Snow Harris of Plymouth has resumed the subject, and, by new methods of observation, and instruments of great accuracy, he has confirmed the law given by Coulomb, both in the case of simply electrified conductors, and in bodies upon which given quantities of electricity have been accumulated. A more particular account of these instruments, and of the method of applying them, will be given in a subsequent part of this article.

The law of the attractive force is easily obtained when the opposed surfaces are parallel planes or rings; but in the case of spherical conductors, and bodies of other forms, the conditions become more complicated. Considering the distribution of the electricity on the spheres to be uniform, and the whole force exerted to be as the number of attracting points directly, and as the squares of the distances between the respective points inversely, Mr Harris has shown that the *forces between two spheres will* *be inversely as the distances between their nearest points multiplied into the distances between their centres.*

Mr Harris's experiments on the attractions of spheres and planes.

In order to submit this result to the test of experiment, he used two spheres whose radius was an inch, and obtained, by means of his electrical balance, the following results:

Distance of Centres of Spheres.	Distance of nearest Points by experiment.	Calculated Distance of the Points in each Sphere in which the Force may be supposed to be collected.	Force in Grains.
2·2	0·2	0·664	12·0
2·5	0·5	1·117	4·25
2·8	0·8	1·496	2·25
3·0	1·0	1·732	1·75

These results confirm the law deduced from theory, and Mr Harris has established its truth more completely by extending it to several new cases, the most important of which, with the deductions, are as follows:

1. Two spheres at the distances in column 1, exert the same force as two circular planes of equal areas at the distances in column 3.

2. The attractive force of two opposed conductors is not influenced by the form or disposition of the unopposed portions. The attractive force, for example, is the same, whether the opposed bodies are merely circular planes, or planes backed by hemispheres or cones. Two hemispheres also attract each other with the same force as the spheres of which they are hemispheres.

3. The force between two opposed bodies is directly as the number of attracting points, the distance being the same. Thus two circular planes of unequal diameter do not attract each other with a greater force than that of two similar areas, each equal to the lesser. In like manner, the attractive force between a ring and a circular area of the same diameter is equal to that exerted between two similar rings each equal to the former.

4. The attractive force between a spherical segment and an opposed plane of the same curvature, is equal to that of two similar segments on each other.

SECT. VIII.—*On the Dissipation of Electricity by the Contact of Air, and by Imperfect Insulation.*

Dissipation of electricity by air.

If we place an electrified body upon a mass of gum-lac, which is the worst of all conductors, or the best insulator of electricity, we shall find that, in a certain time, the whole of its electricity has disappeared. In like manner, if we suspend the same body under the same circumstances by a long fibre, or very small cylinder of gum-lac, we shall also find that in this last case the electricity will wholly disappear in a certain time; but the time in this last case will be much longer than in the first case. If we perform the same experiments in rarefied, moist, or hot air, we shall find that the electricity disappears faster than in condensed, dry, and cold air.

In all these cases the electricity is said to be *dissipated;* and it becomes an interesting as well as a most useful inquiry to determine the separate influence of these different causes in carrying off the electricity of electrified bodies.

The only observations which we possess on this subject we owe to the ingenuity and industry of M. Coulomb.

By means of the torsion balance he determined, in four days, two in May, one in June, and the last in July, the ratio of the electric force lost per minute to the total mean electrical force of the body, the electrical density varying in the five or six experiments which were made in each day. The following were the results:

May 28. Ratio of the Force Lost.	May 29. Ratio of the Force Lost.	June 22. Ratio of the Force Lost.	July 2. Ratio of the Force Lost.
$\frac{1}{40}$	$\frac{1}{56}$	$\frac{1}{13\frac{1}{2}}$	$\frac{1}{14}$
$\frac{1}{38}$	$\frac{1}{61}$	$\frac{1}{11}$	$\frac{1}{19}$
$\frac{1}{42}$	$\frac{1}{54}$	$\frac{1}{13}$	$\frac{1}{30}$
	$\frac{1}{58}$		
$\frac{1}{42}$	$\frac{1}{54}$	$\frac{1}{13\frac{1}{2}}$	$\frac{1}{19}$
Mean, $\frac{1}{40\frac{1}{2}}$	$\frac{1}{56\frac{3}{5}}$	$\frac{1}{12\frac{3}{4}}$	$\frac{1}{20\frac{1}{2}}$

Hence, in reference to the state of the atmosphere on the days of observation, we have

	Mean Ratio of Force Lost per Minute.	Barometer Inches.	Thermometer of Reaumur.	Hygrometer of Saussure.
May 28.	$\frac{1}{40\frac{1}{2}}$	28·3	15½°	75°
May 29.	$\frac{1}{56\frac{3}{5}}$	28·4	15½	69
June 22.	$\frac{1}{12\frac{3}{4}}$	27·11	15¾	87
July 2.	$\frac{1}{20\frac{1}{2}}$	28·2	15¾	80

By examining the results for each day in the first of the preceding tables, it will appear that the ratio of the electric force to the whole force is a constant quantity during the same day, or when the air has the same degree of moisture. Hence it follows,

1st, *That the loss of electricity is proportional, in the same state of the air, to the electrical density;* from which it follows, as Coulomb has shown,

2d, *That the ratio of the force lost in a minute to the total force, is double of the ratio of the loss of intensity of each body to the total density.*

From a great number of experiments made with balls of different magnitudes, and when the quantity of electricity, as well as the electrical density of each ball, were very different, he found,

3d, *That the ratio of the dissipation of the electric force during a minute, to the total force, is uniformly a constant quantity.*

By using a globe a foot in diameter, cylinders of all lengths and magnitudes, circles of paper and of metal, &c. he found,

4th, *That when the air was dry, and the degree of electricity not great, the ratio of the decrease of the electrical density to the density itself is always a constant quantity, whatever be the form or the magnitude of the electrified body.*

By using *pith balls,* and balls of *copper* and *sealing-wax,* he found,

5th, *That the law of dissipation is not influenced by the nature of the body.*

It appears, from the second of the preceding tables, that the dissipation increases with the degree of moisture, as indicated by Saussure's hygrometer; and, by comparing the observations, he concluded,

6th, *That the diminution of the repulsive force, or, what is the same, of the electric density, is proportional to the cube of the weight of the quantity of water dissolved in a given quantity of air.* He found also, 7th, *That the dissipation of electricity increases with the temperature.*

In the course of these valuable researches Coulomb ascertained that there was no dissipation along the fibre which supported the electrified bodies which he employed; and he found also that there were other causes of dissipation, which produced effects of a considerable amount, and which yet remain to be discovered.

sipa- by erfect lation.

Having thus determined the laws of dissipation by the contact of air, Coulomb proceeded to inquire into the causes of dissipation along imperfectly insulating bodies. The experiments which he performed for this purpose were made on the same days with those made on the dissipation by air, so that he was able to determine by calculation the portion which was lost by aërial contact, and the portion lost by imperfect insulation.

When a highly electrified ball was suspended by a silk fibre, the dissipation of its electricity was much more rapid than it should have been by the contact of the air, and therefore a part of it was owing to the imperfect insulating power of the silk thread. But when the intensity of the electricity was diminished to a certain degree, the silk fibre was as good an insulator as the gum-lac. A cylinder of gum-lac eighteen lines long did not cease to insulate perfectly till the degree of electricity was nearly *triple* of that which is insulated by the silk fibre.

Coulomb likewise found, that when a silk thread, or hair, or any fine cylindrical electric, began to insulate perfectly, the electrical density of the body which was insulated was proportional to the square root of the length of the support; that is, if a silk fibre *one* foot long insulates perfectly when the electrical density is D, it will require a fibre *four* feet long to insulate perfectly when the electrical density is 2 D, or double.

M. Coulomb's experiments seem to have been made only with one kind of electricity. M. Biot, however, found that the dissipation was nearly the same, whether the insulated body was electrified negatively or positively.

Sect. IX.—*On the Distribution of Electricity.*

stribu- of tricity.

When any body is electrified by presenting it to the prime conductor, the electricity, though it enter at one part of the body, is obviously distributed over the whole of it, as every part of the body gives distinct indications of its new state. It becomes an interesting inquiry, therefore, to ascertain by what powers the electricity is thus distributed over the body; to determine whether it is distributed throughout the substance of the body, or only on its surface; and to discover the laws of its local distribution, whether it exists on single bodies, on two or more equal or unequal bodies placed in contact, and on bodies of different forms.

These various topics have been treated by Coulomb with that ingenuity and sagacity which distinguish all his labours; and his torsion balance is the principal apparatus which was found necessary.

In order to determine whether electricity was distributed over conductors by a repulsive force between the particles of the electric fluid, or by some affinity or electric attraction for one body in preference to another, he found, by using a pith ball and a ball of copper, that the pith ball received exactly one half of the electricity of the ball of copper, and that the ball of copper had no more affinity or electric attraction for the electric matter than the pith ball. This experiment was varied by using a disc or circle of iron ten lines in diameter, and a paper disc of the same size. In this case also he found that the electricity was equally distributed between the two discs; and he obtained the same result by using various other substances, and performing the experiments with a large torsion balance, with globes of five or six inches diameter.

In all experiments of this kind, the two balls must be allowed to remain a short time in contact, as several seconds elapse before an imperfectly insulating ball is capable of acquiring from the other half of its electricity. When the experiment is made with circular discs, the surface of the one must be placed symmetrically on the surface of the other.

Superficial distribution of electricity.

In order to determine whether the electricity pervaded the whole substance of the conductor, or was distributed on its surface, Coulomb provided an electrometer, consisting of a small circle of tinsel, suspended by a fibre of gum-lac, which, when suspended in a cylinder of glass, is so extremely sensible that a force equal to the *sixty thousandth* part of a grain was sufficient to repel the ball of the needle through an arch of more than ninety degrees.

The conductor whose electrical state he proposed to examine was a solid cylinder of wood four inches in diameter, and pierced with several holes four lines wide and four deep. This cylinder was then supported upon an insulating stand, and electrified by sparks from a Leyden jar. He then took a small circle of gilt paper one and a half line in diameter, and about the eighteenth part of a line in thickness, and he insulated it at the extremity of a cylinder of gum-lac a line in diameter.

Having electrified the tinsel of his electrometer, he brought the circle of gilt paper into contact with the surface of the electrified wooden cylinder, and upon presenting the circle to the electrometer it repelled the tinsel with great force. The same circle was then introduced into one of the holes of the cylinder, so as to come in contact with the bottom of the hole, and rest upon it. When it was taken out, without touching the sides of the hole, and presented to the electrometer, it gave no indications of electricity. In the first case, the small circle carried off electricity from the part of the surface which it touched; but in the second case it carried off none, so that there was no electric matter in the interior of the cylinder, even at the depth of four lines.

Pl. CCXI. Fig. 4.

These curious results, thus established by accurate observation, may be proved by two very pretty experiments, which have been given by Biot. Let S, fig. 4, be a spheroid of conducting matter, suspended by a perfectly insulating fibre A of gum-lac. Form two cups BC, made of gilt paper or tinfoil, or any other conducting material, so as to fit exactly the spheroid when united, and fix to each of them an insulating handle L, L of gum-lac. Electrify the spheroid S, and holding a cup in each hand by the handles L, L, apply them, as in the figure, to the surface of the spheroid. Upon withdrawing the cups, it will be found that they have abstracted from the spheroid S all its electricity, and that so completely, that it will not affect the most delicate electrometer, while the cups will be found to possess the same quantity of electricity which originally existed in the spheroid.

Fig. 5.

The other experiment of M. Biot is shown in fig. 5, where AB is an insulated cylinder, moveable round a horizontal axis, and which may be turned by the winch H, composed of several rods of glass. Around the cylinder there is wrapped a metallic ribband CD, whose extremity D terminates in a semicircle, and is attached to a silk cord F. This apparatus is made to communicate with an electroscope E, composed of two linen threads carrying two pith balls. When the metallic ribband is electrified, the balls and the threads will diverge. Upon unrolling the metallic ribband, by pulling the silk thread F, the pith balls at E collapse, and indicate a diminution of the electrical repulsion; and if the ribband be sufficiently long, compared with the electric charge given to the apparatus, the separation of the balls may become quite insensible; but they will again diverge, and indicate an increase of electrical intensity, if we again roll up the ribband upon the cylinder.

Method of measuring the distribution of electricity.

Having thus ascertained that electricity occupies the surfaces of conductors, the next point to determine is the law of its distribution in bodies of different forms, that is, to ascertain its intensity, or the electrical density, at different points of the surface.

Pl. CCXI. Fig. 6.

The following was the method used by Coulomb for this purpose: In the balance with which he made his first experiments he suspended his needle by a fine silver wire. He then took a cylinder of gum-lac, and having bent it as shown at *ced*, he attached to it a circle of gilt paper *d*, five or six lines in diameter, and the eighteenth part of a line thick. Having electrified the body whose electrical density was to be ascertained, he electrified the disc, carried by the needle by means of an insulated pin as formerly, and then touched the circle *d* with any part of the body where he wished to ascertain the electrical density. This circle was then placed in the balance, and the quantity of its electricity measured. Hence, as the quantity which the circle acquires by its tangential contact with the body is either the same as that of the point which it touches, or proportional to it, it became easy to ascertain the electrical density of different points of conductors, by touching those points with the circle *d*, and subsequently measuring its electricity. During the time, however, which elapses between different observations, a part of the electricity will be dissipated, so that an error is necessarily introduced in comparing the electrical density of any two points *a* and *b*. In order to correct this error, he proceeds thus: Having measured the electricity in *a*, he then, after an interval, suppose of three minutes, measures the electricity in *b*. He then remeasures the electricity in *a* three minutes after he measured the electricity of *b*, and the mean of these two measures for *a* will be the electrical density of *a* at the time when that of *b* was measured.

Distribution of electricity on a globe;

By the method now described Coulomb measured the distribution of electricity on a conducting sphere, and he found that the electrical density was the same on every part of it.

on the surface of a cylinder.

In a similar manner Coulomb found that the electrical density on the middle of the cylinder is to that of its extremity as 1·00 is to 2·30; that the density of the middle was to that of a point two inches from the extremity, as 1·00 to 1·25; and that the density in the middle was to that of a point situated in the hemisphere which terminated the cylinder, and one inch from its extremity, as 1·00 to 1·80. Hence it appears that the electricity is very much condensed upon the two last inches at the extremity of the cylinder, and that it varies very slightly from the middle to within two inches of the extremity.

Relative electrical densities of two globes in contact.

From various experiments, conducted in a way analogous to that already described, Coulomb obtained the following results relative to the manner in which the electrical fluid distributes itself between two globes A, B, of different diameters, after they have been placed in contact, and separated, so that the electricity is distributed uniformly over their surfaces.

Ratio of the Radii of the Globes.			Ratio of the Surfaces of the Globes.			Ratio of Electrical Densities.		
A		B	A		B	A		B
1	to	1	1	to	1	1	to	1
1	...	2	1	...	4	1·08	...	1
1	...	4	1	...	16	1·30	...	1
1	...	8	I	...	64	1·65	...	1
1	...	Infinity.	1	...	Infinity.	2·00	...	1

In order to explain this table, we shall take the case of two globes 6¼ inches and 24 inches, which were actually used by Coulomb. The small globe of 6¼ inches having been electrified, it was touched with the other globe of 24 inches, and when they were separated, so that the electricity of each was uniformly diffused over their surfaces, it was found that the *quantity* of electricity possessed by the large globe was to that possessed by the small one as 11·1 to 1; but as the surfaces of the two globes are as 14·8 to 1, a greater ratio than the other, it follows that the two globes are not charged with electricity in a ratio as great as that of their surfaces; that is, a given area on the small globe contains a greater quantity of electricity, or has a greater electrical density, than the same area in the large globe. The electrical densities in the third column are therefore found by dividing the ratio of their surfaces by the ratio of the quantities of fluid which they contain, and the quotients will be the ratio of the densities given in the third column. Thus, in the present case, 14·8 ÷ 11·1 = 1·3333, the electrical density of the small globe 6¼ inches in diameter, that of the large one of 24 inches being 1.

Two eq globes.

Such is the electrical state of two electrified globes when placed at a distance. It now becomes a curious point to ascertain how the electricity is distributed when one or more equal or unequal globes are in contact. When two equal globes are in contact, the thickness of the stratum of electricity, if it varies in thickness, or the electrical density, if it is equally thick, is nothing at the point of contact, but increases from the point of contact equally in different azimuths to the opposite point of the globes, where it is a maximum. This law of increase varies with the ratio of the diameters of the globe.

Two un equal globes.

In the case of two equal globes, the electrical densities at different distances from the point of contact were as follows:

Distances from the Point of Contact.	Ratio of Electrical Densities.
0°	0
20	0
30	1
60	3·72
90	4·78
180	5·03

When two unequal globes are in contact, the one being *twice* the size of the other, the density of the small globe was almost nothing at 30°. From 60° to 90° it increased in the ratio of 10 to 17, and from 90° to 180° in the ratio of 75 to 100.

When the one globe was *four* times the size of the other, the density of the *small one* was nothing up to 30°, from 30° to 45° it rose to 1, at 90° it was 4, and at 180° it was 5·72. The density of the *large globe* was nothing to the fourth or fifth degree from contact. From this point it increased rapidly, and from 30° to 180° it was almost uniform.

If we separate the two unequal globes, a curious phenomenon takes place. At a certain distance, which is not great, the point of the little globe which was in contact with the larger globe, and which had no electricity, now shows *negative* electricity till they are farther separated. At a certain distance the electricity becomes again nothing, and at a greater distance the same point becomes *positive*.

When the large globe is eleven inches in diameter, and the small one eight, and both positively electrified, the point of the large globe which touched the small one is always positively electrified, whatever be the distance of the two. The similar point of the small globe, however, will be negatively electrified till the distance of the two is *one* inch, at which distance the electricity becomes nothing, and beyond it it becomes positive. If the small globe is only four inches in diameter, the same phenomena take place, but at the distance of two inches and five lines.

veral nal bes.

When *six* equal globes, two inches in diameter, were placed in one line in contact, and electrified, and then examined by the torsion balance, Coulomb found that the electrical density of the *first* was to that of the second as 148 to 100, and that of the *first* to that of the *third* as 156 to 100. When twelve similar globes were similarly placed, the density of the *first* was to that of the *second* as 150 to 100, and that of the *first* to that of the *sixth* as 170 to 100. When twenty-four similar globes were similarly placed, the electric density of the *first* was to that of the *second* as 156 to 100, and to that of the *twelfth* as 175 to 100. At equal distances from the extremities of the row the electric densities were equal, and the density always least in the middle.

The last series of Coulomb's experiments which we shall notice at present, are the highly important ones relative to the distribution of electricity between a globe and cylinder. When the globe was *eight* inches in diameter, and the cylinder thirty inches long, he obtained the following results:—

Diameter of Cylinder.	Mean Electric Density of the Globe to that of the Cylinder.
24 lines	1 to 1·30
12	1 — 2·00
2	1 — 9·00

Hence the electrical densities of different cylinders are in the inverse ratio of the power $\frac{4}{5}$ of their diameter, which approaches very much to unity when the diameter of the globe is very much greater than that of the cylinder.

When the globes are different, and the cylinders remain the same, the electric density of the cylinders will vary as the diameters of the globes, if their diameters are much greater than that of the cylinder. Hence, calling D the mean electric density of the globe, d that of the cylinder, R the radius of the globe, and r that of the cylinder, we have $d = \frac{m\mathrm{DR}}{r^{\frac{4}{5}}}$ or $d = \frac{m\mathrm{DR}}{r}$, when R is much greater than r. Coulomb found the constant co-efficient m to be $\frac{9}{48}$.

Sect. X.—*On the Action of Points, and on Electrical Rotations.*

ction of oints.

The influence of points in silently drawing off electricity from a conductor has already been mentioned, and also their influence in discharging electricity from any conducting body in which they are fixed. Both these effects are distinctly seen if a person insulates himself by standing on a stool with glass feet, placed near an electrified prime conductor. If he takes in his hand a rod of metal with a ball at one end and a sharp point at the other, and holds the point at a certain distance from the conductor, he will be able to electrify himself in consequence of drawing the electricity from the conductor, whereas if he holds the ball at the same distance, he will receive no electricity at all. On the contrary, if he connect himself with the prime conductor by a chain till he is charged with electricity, and then throws aside the chain, he will not be able to discharge the electricity quickly from his body by holding out the ball, whereas if he holds out the rod with the point, the electricity will be rapidly discharged from it, and will be seen streaming out from it in the dark.

The experiments contained in the preceding section afford a beautiful and satisfactory explanation of the action of points. We have already seen that the electricity communicated to a cylinder is so distributed that the electrical density of the extremity is 2·30, while that at the middle is 1; and that when the electrical density of a globe is 1, that of a cylinder two lines in diameter and thirty inches long is 9. But we may consider points as cylinders of small diameter and great length, and, following the result now mentioned, we shall find that the electrical density at the rounded extremity of a cylinder two lines in diameter will be $9 \times 2{\cdot}3 = 20{\cdot}7$, while that of the globe which the cylinder touches is only one. In order to make this plain, we have represented in fig. 7 a cylinder or rod AB, in which the ordinates of the curve McN represent the electrical density at different points of the cylinder, or the thickness of the stratum of electricity at these points. The ordinate *cd* being 1, the ordinates AM and BN will be 2·3. But it may be shown, from the law of repulsion, that the re-action of the electric fluid upon the adjacent air varies as the square of the thicknesses of the electric strata, or as the squares of the electric densities. Hence the squares of the ordinates *cd*, AM, or 1, and $2{\cdot}30 \times 2{\cdot}30 = 5{\cdot}27$, will represent the re-action at *d* and A, that is, the electric fluid will have five times the tendency to escape at A, from what it has at *d*.

Pl. CCXI. Fig. 7.

When the point A is connected with a ball B, as in fig. 8, the tendency of the electric fluid to escape at A will be seen from the ordinates of the curve BM, the ordinate at A being very great. We have already seen that the ordinate AM, or the electrical density at A, is 20·7 times as great as the electrical density at B. Hence $20{\cdot}7 \times 20{\cdot}7 = 428{\cdot}49$ will represent the tendency of the electricity to escape from A, the tendency to escape from B being only one. But this tendency to escape is resisted by the air; and as the amount of resistance varies with the density, moisture, and temperature of the air, there will obviously be some degree of electrical density which will overcome that resistance. This result experience completely confirms, for even in the common state of the air a very great quantity of electricity is not necessary to make its way from a pointed conductor.

Fig. 8.

This tendency of points to discharge their electricity against the resisting air, enables us to perform some beautiful electrical experiments, in which a motion of rotation is effected.

Electrical rotation. Fig. 9.

Exp. 1. If one, two, or any other number of wires are placed, as in fig. 9, so as to have beneath their centre of gravity A, a hollow cup, which rests on the top of an insulated stand AB; and if the points *m*, *o*, *n*, *p* of these wires are made short, and are turned in the same tangential direction; then, if we connect them with the prime conductor by a chain C, so as to electrify them, the electricity will issue from each point; and as it will be resisted by the air against which it presses, the arms will turn round in a direction opposite to that in which the electric fluid is discharged, in the very same manner as the rotatory motion is effected in Barker's mill. In the dark a stream of light will exhibit the discharge of the electricity, and when the velocity of rotation becomes sufficiently great, the four streams will form a beautiful circle of light.

Electrical orrery. Fig. 10.

Exp. 2. The *Electrical Orrery*, as it is called, is founded on the same principle. A spherical ball of metal S, fig. 10, representing the sun, has its inner concave surface supported on a pivot on the top of an insulated stand CD. From the ball S extends a wire SE, the turned-up extremity of which supports upon a pivot another ball E, which represents the earth, having a wire passing through it, and carrying at one end a small ball M, representing the moon, while the other end is bent into a sharp point *m*. A sharp point H is also fixed to the arm EF. If these balls are electrified as in the last experiment, by a chain A connecting them with the prime conductor, the discharge of electricity from the point H will give a rotatory motion to the arm CE and the earth E, while the electrical discharge from the point *m* will give a rotatory motion to the moon M round the earth E. In this manner the moon revolves round the earth, while the earth and moon are together carried round the sun.

Electrical bells.

Exp. 3. By the same principle a chime of bells may be rung in a more elegant manner than that which is exhibited in fig. 4, Plate CCIX. Five cross arms of wire are made to revolve upon the pivot A of an insulated stand AB, as shown in fig. 11, and each wire has its extremity pointed and turned in the same direction. To one of these arms C, which is purposely made longer than the rest, is suspended a glass ball or clapper *b*, by a silk thread *ab*, and immediately behind it a rod CD. Eight bells are placed upon the stand, and if a chain connects the point A with the prime conductor, the discharge of the electricity from the points will move the cross arms round, and cause the clapper *b* to ring the bells during its revolutions.

Fig. 11.

Electrical inclined plane.
Fig. 12.

Exp. 4. The electrical inclined plane, shown in fig. 12, acts upon the same principle. Two straight parallel wires, MO, NP, are stretched upon the insulating stands M, N, O, P, fixed on a base of wood. Across these wires is placed a wire *ab*, having another wire *cd* at right angles to it, terminated by two bent points lying in a plane passing through *cd*, and at right angles to *ab*. When the apparatus is electrified by a chain, the electricity is discharged at the points *a*, *b* in a vertical plane, the wires revolve, and the wire *cd* rolls up the inclined plane, in opposition to the force of gravity.

SECT. XI.—*Explanation of the Phenomena of Electrical Attraction and Repulsion.*

Electrical attraction and repulsion.

In order to explain the phenomena of attraction and repulsion which have been already described, we must avail ourselves of several principles which have been either previously deduced from experiment, or which may be readily proved.

1. The electric fluid has a tendency to escape from all electrified bodies, whether conductors or non-conductors, in consequence of the mutual repulsion of its particles.

2. The electric fluid is prevented from escaping from bodies so rapidly as it would otherwise do, by the pressure of the air with which they are surrounded, and which is itself a bad conductor of electricity.

3. If the pressure of the air is increased, the escape of the electricity is diminished; and if the pressure of the air is diminished, the escape of the electricity is increased.

4. In *conductors* the electric fluid passes with the utmost facility and rapidity among the material particles, and does not seem to be in any way acted upon by them.

5. In *non-conductors* the electric fluid escapes from them, and moves among their material particles with difficulty; so that there is some force by which the electric fluid adheres to or is detained by the material particles of non-conducting bodies.

With the aid of these principles, we are now able to explain the three different cases of electrical attraction and repulsion.

Pl. CCXI.
Fig. 13.

1. *When the two bodies are non-conductors.* Let A be a fixed electrified non-conducting body, and B another of the same kind capable of moving. The particles of the electric fluid in A will repel each other; but this repulsive force cannot produce any motion on the centre of gravity of the ball, as their united tendency is to produce rest. The same is true of the repulsive force of the electric fluid in B. Let us suppose that A and B are both electrified *positively*, or both *negatively*, then the repulsion between the electric fluid in A, and that in B, will cause B to recede from A, because the electric fluid in B adhering as it were to the particles of B, cannot recede from A without taking the body along with it. In like manner, if A is *positive* and B *negative*, or *vice versa*, the attraction of the positive electric fluid for the negative electric fluid will cause the electric fluid in the moveable body B to approach to that in A, and, by its bringing the material particles along with it, will produce the phenomena of attraction.

Hence it follows that the attractions and repulsions of non-conducting bodies are produced by the attractions and repulsions of the electric fluid, which, from its adhesion to their matter, causes them to partake in its motion.

Fig. 1
15.

2. *When the one body is a non-conductor, and the other a conductor.* Let A, fig. 14 and 15, be a fixed and *non-conducting* body, and B a moveable and conducting body. When these two spheres are separate, the electric fluid is distributed on the surface of each in a stratum or thin shell of equal thickness; but when they are brought near each other, the fluid is distributed as in fig. 14, when A and B are *oppositely* electrified, and as in fig. 15, when they are *similarly* electrified; the space between the dark circles and the dotted outlines representing the section of the stratum of electrified fluid upon each sphere. The arrangement of the fluid in fig. 14 is produced by the attraction of the fluid in A for the fluid in B, and *vice versa*, producing an accumulation of it on each sphere on the sides nearest one another; and the arrangement of the fluid in fig. 15 is produced by the repulsion of the two opposite fluids, producing an abstraction of the fluid from the sides nearest one another, and an accumulation of it on the sides farthest from each other. But since the non-conducting sphere A is fixed, the adhesion of its fluid to its material particles cannot produce any motion; and since there is no adhesion between the fluid in the conductor B and its material particles, these particles, or the body which they compose, cannot move along with the fluid. The accumulated fluid, however, at the points O, O, fig. 14 and 15, tends to escape from the spheres in virtue of the mutual repulsion of its own particles; but it is restrained by the pressure of the air, which re-acts upon it. But the pressure of the air is an uniform force on every part of the sphere; and as the force with which the electric fluid resists this uniform pressure is greatest at the sides O, O, the ball B, in fig. 14, will recede in virtue of this force from A; and the ball B, in fig. 15, will from the same cause approach to A. The *attraction*, therefore, of the two *opposite* fluids in fig. 14 produces, through the agency of the atmosphere, a *repulsion* of the moveable sphere; and the *repulsion* of the *similar* electric fluids in fig. 15 produces, through the same agency, an *attraction* of the moveable to the fixed sphere.

Hence it follows that the attractions and repulsions of two bodies, one a conductor and the other a non-conductor, are merely apparent, and are produced solely through the agency of the atmosphere.

3. *When the two bodies are conductors.* In this case the phenomena will be nearly the same as in the last; for, by making A a conductor, we have only removed the adhesion between its fluid and the particles of which the body is composed, a force which was not brought into play in case 2, owing to A being fixed.

henome-a and Laws.

In the preceding observations we have taken no notice of the decomposition of the natural electricities of the two bodies, as the reader is not yet prepared for this consideration. We have supposed one of the spheres to be fixed and the other moveable, merely to simplify our illustrations; but it is obvious that the same effects would have been produced, but only with different degrees of intensity, if the two spheres had been moveable.

In order to show that apparent attractions and repulsions may be produced by the mere resistance of the air, and without any mutual action between the particles of the two bodies which are attracted and repelled, M. Biot has employed a very happy illustration, on which we have ventured to make a slight improvement. Let B, fig. 16, be a glass globe filled with water, and suspended by a string A. Make a hole in two opposite points of it, C and D, from which the water can flow, and having closed them with wax, fill the globe with water. With a burning mirror M, whose focus is at C, condense the sun's rays RR, and melt the little plug of wax at C. The water will instantly rush out, and the globe B will move away from M as if it had been repelled by the mirror. Repeat the same experiment by placing the mirror at M′, N′, and throwing the sun's rays upon the opposite plug D by reflexion from the plain mirror *mn*. The plug D being melted, the water will flow out at D, and the globe B will approach to M, N, the mirror having appeared to repel the globe in the first case, and to attract it in the second, though the motion in both cases arises neither from attractive nor repulsive forces, but merely from an unbalanced pressure at D when the water flowed out at C, and an unbalanced pressure at C when the water was discharged at D.

g. 16.

SECT. XII.—*On Electrical Induction, or the Decomposition of the Combined Electricities by Actions at a distance.*

lectrical duction.

In the preceding sections we have considered the phenomena of electricity as produced by friction, and as communicated or transmitted by conductors to other bodies. But it has been found that electricity may be developed in bodies by the mere influence of an electrified body placed at a distance, and we shall now proceed to investigate the laws which regulate this interesting class of phenomena.

.CCXII. g. 1.

Let AB be a cylindrical conductor supported horizontally upon an insulating stand S, and having hemispherical ends at A and B. Suspend from the points A, B, C, D, E, F, similar pairs of pith balls attached to wires or linen threads, and, having insulated it carefully by the stand S, touch it with the finger in order to see that it contains no free electricity. Let an electrified sphere M be now brought near it, so that A, B, M are in the same straight line, and that no spark can pass from M to B. When this has been done, it will be observed that the pith balls diverge as in the figure, the divergency being a maximum at A and B, and equal at these points, becoming less at C and D, where it is also equal, and still less at E and F, where the equality of divergence still exists. Between E and F there will be found some neutral point where the pith balls exhibit no divergence, and this point will shift its position according to the distance of the electrified body M. If we now suspend an unelectrified pith ball by a silk thread, and bring it near to different parts of the cylindrical conductor, we shall find that it is attracted to it in all places except the neutral point between E and F.

From these experiments we are led to the important and curious result, that an *unelectrified body may be electrified by the influence of an electrified body acting upon it at a distance.* The electricity is in this case said to be *induced*, and the phenomenon is called *electrical induction.*

Phenomena and Laws.

If we now electrify the pith ball which was suspended by a silken thread, and bring it near to the cylinder AB, we shall find that it is *attracted* by one half of the cylinder from A, for example, to the neutral point between E and F, and *repelled* by the other half from B to the same neutral point.

From this experiment we infer that *the electricity on one half of the cylinder, from one extremity to the neutral point, is POSITIVE, while the electricity in the other half is NEGATIVE.*

Bring the electrified pith ball near the electrified body M, and it will be found that, if it was formerly repelled from B, it will be attracted by M, and *vice versa;* so that we conclude that *the electricity induced upon the half of the cylinder nearest the electrified body is always opposite to that of the electrified body.*

If we now measure the electricity of the body M, both before and after the preceding experiments, and make allowance for the dissipation of it through the agency of the adjacent air, we shall find that no part of its electricity has been communicated to the cylinder AB; and if, while the cylinder AB is electrified by the inductive influence of M, we either remove M to a distance, or discharge its electricity by touching it with the finger, the electricity of the cylinder AB will instantly disappear. In like manner, AB will recover its electrical state the moment that M is brought near it.

Hence it follows that *the positive and negative electricities developed in a conducting body by the presence of an electrified body are not communicated to it by that body, but have existed in a state of combination in the substance of the conductor, and have only been separated from their state of combination by the action of the electrified body.*

As the intensity of the *positive* electricity, as well as its quantity, is the same in one half of the conductor as that of the *negative* electricity is in the other half, and as there is no remaining or *free* electricity in the cylinder AB when the body M is withdrawn, it follows that the union or recombination of the two electricities has neutralized or saturated each other. But as the two united electricities have not been destroyed by their union, they exist in a new state, which is called the *natural electricity* of bodies. The electricity, therefore, which thus naturally resides in conductors, consists of equal quantities of *positive* and *negative* electricity, which neutralize each other's action, and are consequently incapable of producing any of the phenomena of *free* electricity, or of a portion of positive or negative electricity existing in a separate state.

With these explanations, we are now able to understand how the cylinder AB is electrified by the influence of the electrified body M. We have clearly proved, by direct experiment, that bodies similarly electrified repel each other, while bodies oppositely electrified attract each other; and we have shown in Section X. that this repulsion and attraction does not take place between the material particles of the bodies, but between their electricities, or the electric fluids which they respectively contain. Hence we may enunciate the law in the following manner: *Similar electricities repel each other, and dissimilar electricities attract each other.* Now when the sphere M, which we shall suppose to be electrified positively, is brought near the cylinder AB, in which the electricity exists in its natural or combined state, it will repel all the *positive* electricity, and attract all the negative electricity, overcoming the tendency which each has to diffuse itself in virtue of the mutual repulsion of its own particles, and the tendency which the two opposite electricities have to recombine by their mutual attraction. Hence all the *nega-*

tive electricity will be *attracted* to and occupy the half FB of the cylinder, and all the *positive* electricity will be *repelled*, and occupy the remoter half EA. If M is *negatively* electrified, the opposite effects will be produced. Let the body M be now withdrawn, the repulsive and attractive forces which it exercised upon the natural electricity of AB will cease, and the two electricities, separated by its action, will recombine by their mutual attraction, as well as by the mutual repulsion of the particles of each, and the cylinder AB will be restored to its natural state of electricity.

The principle of electrical induction which we have now illustrated enables us to give a satisfactory explanation of the phenomena of attraction which have been described in Section II. It was there shown that electrified bodies attracted light and unelectrified bodies that were brought near them; but it will now appear that these apparently unelectrified bodies were first electrified by induction, and, in consequence of the decomposition of their natural electricities, were attracted by the excited body. Thus, if M, Plate CCXII. fig. 1, is an electrified body placed in a perfect vacuum, and AB a small light body suspended near M, and capable of moving towards it, then AB will be so electrified by the influence of M, that the electricity of the same name as that of M will be accumulated in the half FB of the cylinder, and the other electricity in the half EA. But the electricity of M attracts that of BF more powerfully than it repels that of EA, and consequently the light body AB will be attracted to M in consequence of the previous decomposition of its native electricity. If this decomposition cannot be effected by M, or if it takes place with difficulty, the body AB will not be attracted, or will be attracted less readily. M. Biot has illustrated this position by the following simple experiment. Suspend by fine silk threads two small balls of equal dimensions, one of them being made of pure gum-lac, and the other of gum-lac either gilt on its surface or covered with a thin plate of tinfoil. When these two balls are placed beside each other, and at a small distance, bring near them an electrified tube of glass or sealing-wax, and it will be seen that the gilt ball will be more strongly and easily attracted than the other. The uncoated ball of lac will not begin to be attracted till after a certain time, when the decomposition of its natural electricity has been effected; and thus its electrical state will continue after the removal of the electrified body. The first ball, though gilt, acquires also in this manner a permanent electricity, because the gum of which it is composed is impregnated with the electricity developed at its surface, and both of them are in this respect assisted by the contact of the air, which, under the influence of the electrified body, tends especially to carry off from them the one of the two electricities, which is repelled by this body, while it has less effect upon the other, whose proper repulsive force is concealed by attraction. Hence, says M. Biot,[1] we observe in general, that insulated bodies which have for some time been under the influence of an electrified body, end in having an excess of electricity of a kind opposite to its own, and the effects of which are seen when they are withdrawn from the influence of that body.

Pl. CCXII. Fig. 1.

In examining the action of M upon AB, fig. 1, we supposed that no change took place in the electrical condition of M; but this is not the case, for the body AB, as soon as its natural electricity has been decomposed, begins to re-act upon M, through the agency of its separated electricities. These separated electricities not only tend by their attractive and repulsive forces to change the distribution of the free electricity which exists in M, but also to decompose its natural electricity, and thus to increase its free electricity by one of the two separated electricities. When this change has been effected upon the electrical state of M, its action upon AB will also change. It will decompose a new quantity of the natural electricity of AB, and distribute the positive and the negative electricities of which it is composed in the halves AE, BF; and these new portions will again re-act upon M, till a permanent equilibrium is effected among all the attractive and repulsive forces which are thus brought into play.

Supposing such an equilibrium to be established between the two bodies M and AB, we shall proceed to examine the phenomena which are produced by the introduction of a third body. For this purpose let AB represent the conducting cylinder, and M the electrified body, as in fig. 2. Let an insulated conducting body O, in its *natural state* of electricity, be now brought near AB, so as to touch it, and let us suppose that the electricity of M is *positive*, and consequently that the electricity in the half BE is *negative*, and that in AE *positive*. If we now remove the body O, and examine its electrical state, we shall find that it has acquired *positive* electricity, and we shall observe that the divergency of the pith balls at A has diminished, while their divergency at B has increased. If we again remove the cylinder AB from the influence of M, or remove M from it, we shall find that AB is charged with *negative* electricity. Previous to the contact of O with A, the *positive* electricity in AE repels the *negative* electricity in M, and attracts the *negative* electricity in BE. Hence it contributes by both these actions to weaken the attraction of the *positive* electricity in M for the *negative* electricity in BE, and its repulsion for the positive electricity in AE. But when, by the contact of the third conductor O with the end A of AB, we withdraw a portion of the positive electricity in AE, we at the same time increase the attraction between M and BE, and the repulsion between M and AE, by diminishing the force by which that attraction and repulsion were weakened. Hence the increased action of M will decompose an additional portion of the natural electricity of AB, drawing the *negative* part of it to EB, and repelling the *positive* part of it to AE. The electricity, therefore, which is accumulated at B or in EB is greater than that accumulated at A or in EA, because the third conductor O has taken away a part of the positive electricity in AE. Hence, when we remove AB from the influence of M, so as to allow its separated electricities to re-combine, there is an excess of negative electricity, with which of course AB will be found charged. It is therefore obvious that the divergency of the balls should be greater at B than at A, as was found to be the case from the excess of *negative* electricity which existed at B while the cylinder was under the influence of M.

Pl. CC I. Fig. 2.

In the experiment, as above described, the third conductor O was insulated, and could therefore carry off only a portion of the positive electricity in AE, corresponding to its size: but if we use a conductor which communicates with the ground, the whole of the free electricity in AE will escape; the pith balls at A will exhibit no divergency, while those at B will diverge still more than they did formerly; and this divergency will suffer no diminution by again touching the end A with the insulated conductor. If the conductor AB is now removed out of the influence of M, the divergency of the balls at B will be still further augmented. The cause of these phenomena is very obvienome-na and Laws.

---

[1] *Traité de Physique*, tom. ii. p. 233-4.

ous. When all the positive electricity in AE has escaped into the earth, it no longer counteracts the action of M upon BE, so that this action is augmented; and the consequence of this is, that M decomposes a fresh portion of the natural electricity of AB, the positive part of which passes off, by the mutual repulsion of its own particles, into the earth, while the resinous part is collected in BF, and increases the divergency of the balls at B. Hence, when AB is removed from the influence of M, the excess of *negative* electricity will be greater than previously, and the divergency of the balls at B will increase conformably with observation. The very same phenomena will be observed if the body M is charged with *negative* electricity, and may be described in the very same words by changing only the terms *positive* for *negative* and *negative* for *positive*.

CHAP. II.—ON THE ELECTRICITY PRODUCED BY HEAT, PRESSURE, AND SEPARATION OF PARTS.

In the preceding chapter we have given a general and popular view of the phenomena of electricity, and we have explained the remarkable phenomena of electrical induction. In our experiments and observations on these subjects we have made use of the electricity which is generated by the friction of tubes of glass or sticks of sealing-wax, or which is obtained from the common electrical machine. But electricity can be obtained from various other sources, and its properties are the same, from whatever source it is obtained, provided it is used in the same quantities and of the same intensity.

As there is no part of the science more interesting to the general reader than that which relates to the different modes in which electricity can be obtained from organized and unorganized bodies, we shall enter fully into this branch of the subject, and shall treat, in successive chapters, of the electricity produced by heat and pressure, by change of form and separation of parts, by animal bodies, and by the elements of our atmosphere.

SECT. I.—*On Pyro-electricity, or the Electricity produced in Minerals by Heat.*

ro-elec-city.

In our history of the science we have already given a general view of the progress of discovery in this interesting branch of electricity. We shall now, therefore, proceed to describe the phenomena which are developed by heat in various minerals and artificial salts.

1. *On the Pyro-electricity of Tourmaline.*

urma-e.

The tourmaline is a very common mineral, which crystallizes in long slender prisms. Its primitive form is an obtuse rhomb, the axis of which coincides with the axis of the prism. It has also one negative axis of double refraction, which is coincident with the axis of the rhomb; and it possesses some remarkable properties in reference to the absorption of common and polarized light, which will be described in another article. This mineral acquires *vitreous* electricity by friction; and when two tourmalines are rubbed together, the one acquires *vitreous* and the other *resinous* electricity.

In order to observe the electricity which heat develops in certain minerals, we have found it convenient to use the thin internal membrane of the *Arundo Phragmites*, which was cut with a sharp instrument into the smallest pieces, or, what is still better, the thin transparent scales which cover the buds of several plants of the genus *Pinus*, and which are pushed off at the expansion of the bud in spring. These minute fragments are well dried, and the pyro-electricity of any mineral is determined by its power of lifting one or more of these light bodies after the mineral has been exposed to heat. When we wish, however, to determine the kind of electricity which is developed in any pole of a mineral, we must employ a small instrument, called an electroscope, such as that used by Haüy, which is shown in Plate CCXII. fig. 3, where AB is a needle of silver or brass, terminated on one side by a globule B of the same metal, and on the opposite side by a small bar or narrow plate G of transparent Iceland spar, fixed to A by wax or any other means. This needle carries at its middle point D a cup of rock-crystal, by which it rests on a steel pivot at the upper end of the piece of wire D, fixed in a cylinder E of gum-lac or sealing-wax. A small weight G is made to move along the arm BD to balance the needle in a horizontal position. In order to prepare this little instrument for observation, take the lever by the end B, with the right hand, and with two of the fingers of the left hand press two of the opposite faces of the crystal G, and then place the lever upon its pivot D. Haüy calls this apparatus a *vitreous* or *positive* electroscope.

Phenomena and Laws.

Haüy's vitreous electroscope. Pl. CCXII. Fig. 3.

The *resinous* or *negative electroscope*, which is shown in Plate CCXII. fig. 4, differs from the preceding only in having a simple needle of silver or copper AB, with two globules A, B at its extremities, and having a cup C of the same metal. In order to prepare this electroscope for use, a stick of sealing-wax is rubbed with a piece of woollen cloth, and then made to touch one of the globules of the needle, which is immediately repelled.

Haüy's resinous electroscope. Fig. 4.

In order to determine the kind of electricity generated in any pole of a crystal by heat, we have only to apply it to either of these electroscopes. If it attracts the globule of the vitreous electroscope, or repels that of the resinous one, its electricity will be resinous; and if it repels the globule of the vitreous one, and attracts that of the resinous one, the electricity will be vitreous.

Haüy's general apparatus. Fig. 5.

Haüy used another apparatus in his experiments with tourmaline, which he considers preferable to all others. A rectangular plate of metal *hk*, bent up at right angles at its two ends *h*, *k*, is balanced on a steel needle *ab* by a cup of agate *x*, which is confined by a circle of silver and two screws *s*, *z*. Towards the extremities of the lower surface of the plate *hk* are fixed two silver wires *pi*, *uy*, having a slightly oblique direction, and terminated by two silver globules *i*, *y*. The use of these little balls is to lower the centre of gravity of the apparatus, so that the plate *hk* may always remain supported during its revolution on the pivot. Let us now suppose that we wish to determine the two kinds of electricity which exist in the poles of a tourmaline. Take one of the Spanish crystals, which is the best for the purpose, both from their thinness and their length, and having heated it either at the fire or at the flame of a spirit-lamp, by holding it in a pair of iron pincers with a wooden handle, place it at *mn*, as shown in fig. 5, in the two notches made on purpose in the bent-up pieces *h*, *k*; and having held near its poles in succession a stick of excited sealing-wax, that pole, *v*, will be the *vitreous* one which is attracted by the wax, and the other, *r*, the resinous one which will be repelled by it.

After measuring the intensity of the electricity in different points of the tourmaline, Haüy found that the electricity was distributed nearly in the same manner as in a cylindrical conductor electrified by induction. The *vitreous* electricity was a maximum near one extremity of the crystal, and gradually diminished towards the middle of the crystal, where it disappeared. Here the *resinous* electricity appeared very faintly, and gradually increased towards the other end of the crystal, near which it was a maximum.

If tourmaline, when rendered electrical by heat, is broken in pieces, each piece will have a vitreous and a resinous pole, whether it is broken from the vitreous or the resinous end, the extremity of the fragment always possessing the same kind of electricity as that of the pole to which it was nearest when it formed part of the crystal.

It had been early noticed that the tourmaline became electrical only at a particular temperature, and that its electricity disappeared at temperatures above and below that particular degree of heat. If we heat the tourmaline beyond this temperature, and allow it gradually to cool, it will soon arrive at that temperature (between 30° and 80° of Reaumur, 99° and 212° of Fahr. according to Æpinus) at which it exhibits its electrical properties. As the temperature falls, its electricity becomes progressively feebler, and finally disappears. Haüy, however, found that other changes take place as the cooling of the mineral increases. At a certain degree of coldness its electricity re-appeared, and gradually increased till it reached its maximum, when it again disappeared gradually. But, what was very interesting, the electricity was not the same as before; the pole which was formerly *vitreous* was now *resinous*![1] It is extremely probable that the same changes would continue to take place both above and below the temperatures at which these two opposite states were produced. Haüy caused the foci of two burning-glasses to fall upon the poles of a tourmaline, and he observed that, after each pole had acquired its electricity, it then ceased to act, and finally exhibited an electricity of an opposite kind.

Haüy has ingeniously explained the phenomenon of each fragment of a tourmaline having two different poles, like the crystal to which it belonged, by supposing that every integrant particle of a tourmaline is itself a little tourmaline with its two poles. "Hence it follows," says he, "that in the entire tourmaline there will be a series of poles alternately vitreous and resinous; and such are the quantities of free fluid which appertain to these different poles, that in all the half of the tourmaline yet unbroken, which manifest the vitreous electricity, the vitreous poles of the integrant molecules are superior in force to the resinous poles in contact with them; while the contrary obtains in the half which manifests the resinous electricity; whence it follows that the tourmaline is in the same state (speaking generally) as if each of its halves were only solicited by quantities of vitreous or resinous fluid equal to the differences between the fluids of the neighbouring poles. Now, if the stone be cut at any place whatever, as the section can only take place between two molecules, the part detached will necessarily commence with a pole of one kind, and terminate with a pole of a contrary nature."

Mr Sievright of Meggetland fitted up a tourmaline so as to bring the action of its two poles very near each other. It resembles the letter D with an opening in its round part, the straight line representing the tourmaline, and the two bent portions are pieces of silver wire rising out of two silver cups, one of which embraces each pole of the tourmaline. If a pith ball, or a ball of sola, is suspended between the two ends of the silver wires, it will vibrate in a beautiful manner, in virtue of their opposite actions. Æpinus, it appears, fitted up the tourmaline in a manner somewhat resembling that which has been described. Sir Humphry Davy has stated the curious fact, which we believe has never been verified by any subsequent observer, that "when the stone is of considerable size, flashes of light may be seen along its surface."[2]

On the Pyro-electricity of thin Plates of Tourmaline.

Pyro-ele tricity o thin pla of tourn line.

The electricity exhibited by ordinary crystals of tourmaline is very feeble; and though two good tourmalines, when floated in water upon corks, will approach and recede from each other when they are excited by a suitable temperature, yet these tourmalines are not capable of lifting one another, or of adhering to an unelectrified body, by decomposing the natural electricity of the part of it with which they are brought in contact.

Pl. CCX Fig. 6.

A method of increasing the electrical action of tourmaline, and of enabling one large piece to lift another, and even to adhere to other bodies, has been used by Sir David Brewster. He cut thin slices out of a large crystal of tourmaline so that they had parallel faces perpendicular to the axis of the original crystal, as represented in fig. 6, where VVVV is the vitreous face of the plate, corresponding to the vitreous pole of the crystal; and RRRR the resinous face; each of these faces being perpendicular to the edge VR of the prism, and consequently to the axis of the crystal. When the two faces of the plates thus formed are ground flat and well polished, one plate will readily lift another. If we place one of these plates upon a piece of flat plate glass, placed horizontally upon a table, the tourmaline will slip off the glass if the latter is slightly inclined to the horizon. But if the glass has been previously heated, the tourmaline plate will adhere to it; and by inverting the glass, the tourmaline will adhere to it even in that position, supporting its own weight by its attraction for the glass. The intensity of the electricity may be easily measured at different temperatures, by ascertaining the angle of inclination at which the weight of the tourmaline overcomes its adhesive force. The plate which exhibits this powerful action obviously consists of an infinite number of minute crystals of tourmaline, with vitreous and resinous poles; and as the point of maximum intensity is situated near the extremity of each crystal, all the vitreous poles will be situated in a plane near the vitreous surface VVVV, while all the resinous poles will be situated near the resinous surface RRRR. If a rectangular plate of the same size, like VVRR, fig. 7, is cut out of a crystal, so that its surfaces are parallel to the axis of the prism, it will adhere to the heated glass plate with much less force than in the preceding case. These plates of excited tourmaline adhere to all metallic bodies, to wax, and to all minerals that have been tried.[3]

If there was no mistake in the experiment by Sir H. Davy, described in a former paragraph, respecting the appearance of a flash of light in a mounted tourmaline, it will doubtless be best verified by mounting several plates of equal thickness, cut out of a broad tourmaline, placing them all in the same plane, and combining their effects in two wires. A powerful little pyro-electrical battery might thus be made, from which both a shock and a flash might be obtained.

Having found that the electricity of plates of tourmaline was more powerful than crystals of it, Sir David Brewster conceived the idea of examining its pyro-electricity, when its fragments were infinitely small, or when it was reduced to the finest powder or dust. The analogy of magnetic bodies led to the notion that the pyro-electricity would disappear, while the results obtained with short prisms in the form of plates strengthened the opposite opinion, that the pyro-electricity might even be increased by this process. He therefore "pounded a portion of a large opaque tourmaline in a steel mortar till it was reduced to the finest dust. I then placed the powder upon a plate of glass, from which it slipped off by inclining the glass, like all other hard powders, without exhibiting any symptoms of cohesion, either with the glass or with its own particles. When the glass was heated to the proper temperature, the powder stuck to the glass; and when stirred with any dry substance, it collected in masses, and adhered powerfully to the substances with which it was stirred. This viscidity, as it were, or disposition to form clotted masses, diminished with the heat, and at the ordinary temperature of the atmosphere it recovered its usual want of coherence."[1]

---

[1] This inversion of the poles was discovered by Mr Canton.

[2] *Elements of Chemical Philosophy*, vol. i. p. 130.

[3] See *Edin. Phil. Journal*, 1819, vol. i. p. 205.

M. Becquerel has lately made some experiments on the pyro-electricity of the tourmaline. He found that when the crystal was of a certain length it became electrical both by heating and cooling; and that crystals of a greater length ceased to become electrical by heating. When the length of the crystal was eight centimeters, or three inches and one ninth of an inch long, they ceased to exhibit electricity either by heating or cooling. M. Becquerel remarks, that if this law is inversely true, that is, for very small lengths, *the atoms of the tourmaline ought to acquire a considerable electrical polarity by the smallest changes of temperature.*[2]

2. *On the Pyro-electricity of the Borate of Magnesia.*

ate of gnesia.

The electricity developed in boracite by heat is considerably less than that of the tourmaline. In 1791 the Abbé Haüy discovered the pyro-electricity of this mineral; but he found it extremely difficult to determine the vitreous and resinous poles. He naturally expected to find two opposite poles, as in the tourmaline; but a succession of attractions and repulsions which took place very rapidly perplexed him extremely. Considering, however, that the boracite was a cubical crystal with three axes, and the tourmaline a rhombohedral one with only one axis, he conceived that the former crystal has a vitreous pole at the one end of each axis, and a resinous pole at the other end. This conjecture he verified by experiment; and the poles were found to be so placed that each alternate pole possessed the opposite electricity: the experiments, however, which are necessary to establish this result require to be made with great care, particularly in reference to the repulsive actions, which take place only within a very limited space; so that, in order to obtain the repulsion of one of the resinous poles on a body which is itself in a resinous state of electricity, we must direct this body exactly to the repulsive point, otherwise it will be attracted towards the neighbouring points, which are in their natural state, or nearly so.

It is a curious fact in reference to the preceding results, that the boracite has been lately found by Sir David Brewster to possess distinct double refraction; and consequently it cannot, as he concludes, have the cube for its primitive form, or three axes of crystallization. He infers that its primitive form is a rhombohedron of ninety degrees, the form which separates the obtuse and acute rhombohedrons; and hence it is a most remarkable circumstance that its electrical poles should be arranged in the manner described by Haüy. We hope, however, to be able to reconcile these discordant results.

3. *On the Pyro-electricity of the Topaz.*

opaz.

The pyro-electricity of the Brazilian topaz was discovered by Mr Canton in 1760. The Abbé Haüy detected the same property in the topaz of Siberia, and found that the poles resided in the two opposite summits of the secondary form of the crystal. Haüy at first thought that the Saxon topazes did not possess pyro-electricity, although they often preserved excited electricity for more than half an hour when the weather was favourable. He afterwards found, however, that they became electrical by heat if previously insulated. Sir David Brewster found pyro-electricity in the greenish-blue topazes of Aberdeenshire.

Haüy observed that the Siberian topazes often preserve their pyro-electricity during several hours, and sometimes from *twenty* to *twenty-four* hours.

Among some topazes which Haüy received from M. Langsdorf, there was one which exhibited resinous electricity at both of its poles, and indications of vitreous electricity in the middle of the crystal. This effect was probably owing to one or more strata of cavities containing fluids, which may have interrupted the distribution of the electricity in the same manner as a fissure.

4. *On the Pyro-electricity of Mesotype.*

Mesotype.

Haüy discovered that some crystals only of this mineral were electrical by heat; but as he was not able to obtain complete crystals, he detached from its support one about five and a half lines long, and found the pyramidal summit to be resinously electrified. *Mem. Instit.* tom. i. p. 54–55. In the first edition of his mineralogy, however (vol. iii. p. 168), he states that the pyramidal summit exhibits *vitreous* electricity by heat, and the fractured end *resinous* electricity; but in the *second* edition of his mineralogy he has omitted altogether that passage, and said nothing whatever on the subject.

The mesotype of Haüy's first edition included the Auvergne mesotype, the apophyllite, the scolezite, and the nadelstein; and therefore it is difficult to say to which of these minerals his observations are applicable.

Sir David Brewster found distinct pyro-electricity in the mesotype of Auvergne.

5. *Pyro-electricity of the Scolezite.*

Scolezite.

The scolezite is a compound crystal, in which the faces of composition are parallel to the axis of the prism. Sir David Brewster found it to possess pyro-electricity, the pyramidal summit having vitreous, and the fractured end resinous electricity.

6. *Pyro-electricity of Mesolite.*

Mesolite.

The mesolite, which has been separated from the scolezite both by distinct chemical and optical characters, is distinguished still further by its being composed of four simple crystals, whose faces of composition are parallel to the axis of the prism, whereas the scolezite consists of two prisms separated by a thin film or vein. Sir David Brewster likewise observed the pyro-electricity of this mineral, and found that its crystallized summit possessed vitreous electricity, and its fractured end resinous electricity, when heated.

7. *On the Pyro-electricity of the Powders of Scolezite and Mesolite when deprived of their Water of Crystallization.*

In the experiments above recited on the powder of tourmaline, the mineral had suffered no other change by trituration than that of being reduced to minute fragments. It became interesting therefore to compare the pyro-electricity of such a powder with that of the powder of a pyro-electrical mineral, on which an essential chemical change had been induced. With this view Sir David Brewster reduced to powder the crystals of scolezite and mesolite, and by the application of heat drove off their water of crystallization, which is doubtless an essential ingredient in every mineral species. When the powder was exposed to a proper heat on a plate of glass, it adhered to it like the powder of tourmaline; and when stirred about by any substance whatever, it collected in masses like new-fallen snow, and adhered strongly to the body which was used to displace it. "This fact," says Sir David Brewster, "is a very instructive one, and could scarcely have been anticipated. As several minerals differ only in the quantity of their water of crystallization, the powder which was thus pyro-electrical could not be considered either as scolezite or mesolite, but as another substance not recognized in mineralogy. The pyro-electrical property, therefore, developed by the powder, cannot be regarded as a property of the minerals of which the powder formed a part, but merely as a property of some of their ingredients. In which of the ingredients, or in what combination of them, the pyro-electricity resides, may be easily determined by further experiments."

[2] *Edinburgh Journal of Science*, 1828, No. xvi. p. 365.

8. *Pyro-electricity of Axinite.*

Axinite.

In his *Manual of the Mineralogist and the Geological Traveller*, M. Braard has stated that some crystals of this mineral become electric by heat. Haüy has confirmed this observation, but no accurate experiments on the position and electricity of its poles have been made.

9. *Pyro-electricity of Calamine.*

Calamine.

So early as 1785 M. Haüy discovered the pyro-electricity of this mineral, which being an oxide of zinc, is the more remarkable, as it is the only metallic body in which this property is very distinctly developed. Haüy found that every crystallized specimen which he tried was pyro-electrical, and that it acquired this property also by cooling. His first observations on the return of the electric action were made on the crystals of oxide of zinc from Limbourg, near Aix-la-Chapelle; and a portion of the acicular variety from the Brisgau. In the winter of 1819 he placed a crystal on a window where the temperature was 11 degrees Cent. below zero, and having left it there a few seconds, he found that it acted very sensibly on a magnetic needle not insulated. He next placed it in a room whose temperature was four degrees above zero, and he observed that its polar action progressively diminished and disappeared. He then brought it within a yard of a fire, and had the satisfaction of observing its polarity return, the pole which was formerly vitreous being now resinous.

10. *Pyro-electricity of Sphene.*

Sphene.

Haüy has found that some crystals of this mineral possess pyro-electricity, but he has not determined the position or nature of its poles.

11. *Pyro-electricity of Prehnite.*

Prehnite.

This mineral crystallizes in right rhomboidal prisms. Haüy found it to be pyro-electrical, and that its poles are in a direction corresponding with the smaller diagonal of the crystal.

12. *Pyro-electricity of other Minerals.*

Other minerals.

The property of becoming electrical by heat has been found by Sir David Brewster to exist in a great number of minerals; and he has given the following list of those in which he succeeded in detecting it:

Calcareous spar.
Beryl yellow.
Sulphate of barytes.
Sulphate of strontites.
Carbonate of lead.
Diopside.
Fluor spar red.
Fluor spar blue.
Diamond.
Yellow orpiment.
Analcime.
Amethyst.
Quartz, Dauphiny.
Idocrase.
Mellite?
Sulphur native.
Garnet.
Dichroite.

13. *Pyro-electricity of artificial Crystals.*

Artificial crystals.

In examining the physical properties of artificial crystals, Sir David Brewster found that several of them, when well dried, were electrical when heated. The following is the list of those in which he detected this property.[1]

Tartrate of potash and soda.
Tartaric acid.
Oxalate of ammonia.
Oxymuriate of potash.
Sulphate of magnesia and soda.
Sulphate of ammonia.
Sulphate of iron.
Sulphate of magnesia.
Prussiate of potash.
Sugar.
Acetate of lead.
Carbonate of potash.
Citric acid.
Oxymuriate of mercury.

Oxalate of lime.

Dr Faraday[2] has more recently discovered a remarkable degree of pyro-electricity in oxalate of lime. Having obtained some of this salt by precipitation, and dried it, when well washed, in a Wedgewood's basin, at a temperature of about 300° Fahr. till it was so dry as not to dim a cold plate of glass held over it, Dr Faraday remarked that, when it was stirred with a platina spatula, it became in a few moments so strongly electrical that it could not be collected together, but flew about the dish whenever it was moved from its sides into the sand-bath. This phenomenon took place whether the salt was placed in glass, porcelain, or metallic basins, or stirred with glass, porcelain or metallic rods. When the particles were well excited and shaken on the top of a gold-leaf electrometer, the leaves diverged two or three inches. The same phenomena took place when it was cooled out of the contact of air. When it was excited in a silver capsule, and left out of contact with the air, the powder continued electrical for a great length of time, proving its very bad conducting power, in which it probably surpasses all other bodies. Dr Faraday remarks, that oxalate of lime stands at the head of all other bodies yet tried, in its power of becoming positively electrical by heat.

14. *On the Connection between the Pyro-electricity of Minerals and their Secondary Forms.*

It is well known that the opposite and corresponding sides of crystals are similar in the number, disposition, and figure of their faces. Haüy, however, found that pyro-electrical crystals deviate from this symmetry, so that there are certain supernumerary planes at one pole which are not seen at the other. This is true of tourmaline, boracite, topaz, and oxinite, and may possibly be found to be a general fact among pyro-electrical crystals, though we do not expect that it will. In the crystals above mentioned, the vitreous electricity resides in that pole where the supernumerary planes are found, and the resinous electricity in the other.

Pl. CC
Fig. 8.

This deviation from symmetry as existing in the tourmaline is shown in fig. 8, where A is the vitreous pole at the summit of a pyramid with *five planes*, and B the resinous pole at the summit of a pyramid with *three planes*.

---

[1] *Edinburgh Journal of Science*, October 1824, p. 212.

[2] *Id.* October 1825; and *Quarterly Journal*, No. 38, p. 338.

The deviation from symmetry in the boracite is more remarkable. The resinous pole at *s*, fig. 9, is marked with one plane, while the vitreous one has the same plane *s* with other three planes *rrr*, fig. 10.

From the preceding facts, Haüy is of opinion that, during the formation of these crystals, the two electrical fluids have influenced, in an opposite manner, the laws by which the crystallization was regulated.

SECT. II.—*On the Influence of Heat upon the Electric Fluid in Metallic Bodies.*

The experiments which have been made on this subject we owe chiefly to M. Becquerel, of whose labours we shall endeavour to give a brief account. It had been long ago shown by M. Desaignes that metallic bodies are capable of electric excitation by heating and cooling. By raising the temperature of one end of a plate of silver, while the other retained the temperature of the surrounding air, he succeeded in producing contractions in a frog, by making the nerve communicate with one end of the plate, and the muscle with the other end. Other philosophers had observed the influence of heat, and they believed that it increased the repulsive force of each of the two fluids. In proof of this they sealed hermetically at a lamp a tube of glass which had been previously electrified interiorly, and by raising its temperature it gave very distinct signs of electricity. M. Becquerel, however, has remarked, that the glass, becoming a better conductor when heated, allowed a portion of the fluid accumulated in the interior of the tube to pass; so that the experiment does not prove that the electrical power of the tube was increased. In order to determine if any does take place, M. Becquerel made the following experiment.

Let AB, fig. 11, be a Leyden jar, at the surface of which is fixed a conductor RS. The jar is closed by a cork *gg*, through which there passes a rod *bb*, fixed at its upper end to a small glass receiver *abc*, and carrying at its opposite end a mass of metal P. When the jar has been electrified interiorly, it is placed in another vessel filled with ice, so that the conducting rod RS is without it. The cork *gg* and the metal P having been taken out, and the mass P heated and replaced as in the figure, the iron P will gradually heat the interior of the bottle without sensibly altering the temperature of its outer surface, which is surrounded with ice. If we then present the button S to an electroscope, there will be perceived an indication of free electricity, and consequently the heat has not increased the action of the electric fluid in the interior of the jar; for if it had done so, the electricity of the exterior surface would have been decomposed, and the rod RS would have communicated to the electroscope the repelled electricity.

But though heat exerts no action on the free fluid, this is far from being true with the natural fluid. When a metallic wire *mm'*, or a series of metallic molecules *m*, *m'*, *m''*, &c. connected together by the force of aggregation, is connected by one of its ends with a heated body, such as a piece of red-hot glass, the moment that the heat enters it this extremity becomes positively electrical, while the negative electricity is driven to the adjacent molecules; but *m'* receiving the heat of *m*, *m''* that of *m'*, &c. the second molecule, which is heated at the expense of the first, takes from this last its positive electricity, and gives to it negative electricity, and so on for all the other molecules. Hence there will arise a series of decompositions and recompositions of the natural fluids while the elevation of temperature lasts.

M. Becquerel's next experiment was to place on the upper plate of Bohnenberger's gold leaf electroscope (taking care to avoid the contact of metals) a platinum wire whose other end is coiled into a spiral. This outer end is brought to a red heat by a spirit-lamp, which is soon withdrawn, and the spiral is then touched with a band of wet paper. After having made the lower plate communicate with the common reservoir, the small band of paper is found to have carried away positive electricity, and negative electricity remains free on the surface of the metal. If we repeat the experiment in an inverse manner, that is, if we hold between the fingers the platinum wire by the end opposite to that of the spiral, and make this last communicate when it is red hot with a band of wet paper, we shall find that the band carries away positive electricity. This result, which takes place also with gold and silver, does not depend on the electricity which is disengaged during the combustion of the alcohol, since the experiment did not commence till the lamp was withdrawn. Nor can it be ascribed to the presence of water in the band of paper, nor to the alteration of the latter by the effect of heat, two causes which are capable of producing electricity, since the same result is obtained when we carry away the positive electricity of the metal by a tube of glass brought to the same temperature as the metal.

In order to make the experiment in this way, take a glass tube of a very small diameter, and whose length is little more than half an inch, and fix to one of its ends a platinum wire one fiftieth of an inch in diameter, soldering it with a lamp. A wire of the same metal, but of a very small diameter, is fixed at the other end of the glass tube, and the largest platina wire is then put in communication with one of the plates of the condenser, avoiding the contact of metals, and the free end of the other wire is held between the fingers. A red heat is then communicated to the end of the small tube to which this last wire is fixed. As its temperature is much higher than that of the other, which is larger and more distant from the focus of heat, and as the tube becomes at the same time a conductor of electricity, the natural electricity of each wire is decomposed. According to the disposition of the apparatus, we shall have the difference of the effects, which will be to the advantage of the small wire, whose end in contact with the tube possesses the highest temperature. In order to obtain this result, it is not necessary to use a heat so high as that of a red heat. By this process we avoid every foreign cause which is capable of modifying the result.

Iron and copper give similar results; but the electric effect produced by oxidation is in this case combined with that of difference of temperature. M. Becquerel has proved that the oxidation is not the sole cause of the electricity obtained with oxidable metals; and he concludes that heat exerts over the natural electric fluid of all metals a similar action, which probably varies in intensity in different metals, according to their nature. With bismuth, tin, and antimony, the effects are scarcely sensible.

The following is Becquerel's theory of the preceding phenomenon. It is an incontestable fact that all bodies contain between their molecules a neutral electric fluid; and M. Becquerel thinks that a rise of temperature establishes round two contiguous molecules an accumulation of opposite electricities, the quantity of which is proportional to this temperature, but whose recomposition is effected without there having been an apparent separation of the two electricities. It is therefore an electrical effect of motion. When the molecules are separated, each of them takes the excess of electricity relative to the portion of electricity which surrounds it.

Pl. CCXII. Fig. 12.

The influence of heat on the natural electricity of metals may be shown by means of the lamp without flame, in the two following experiments given by Becquerel. Let AB, fig. 12, be a copper lamp filled with alcohol, *cc* a tube, and *dd* a cork through which there passes a glass tube EF, covered with a varnish of gum-lac. A cotton wick passes through this tube, one end of it going into the alcohol, while to the other end there is fitted a platina spiral *g*, which becomes incandescent throughout as soon as its temperature is sufficiently raised. By means of this construction the platina spiral communicates with the interior of the lamp only by means of the vapour of alcohol and the wick. If we now place this apparatus on the upper plate of an excellent electroscope, whose lower plate communicates with the ground, and touch the spiral with an ordinary platina wire, it is evident that we carry off the negative electricity which the spiral takes during the combustion of the alcohol, and also the negative electricity furnished by the end of the wire which has the lowest temperature. In this case the spiral will be found to have become positively electrical. If we touch the spiral with a band of wet paper, a contrary result will be obtained; the spiral will become negatively electrical, because the incandescent metal transmits positive electricity to the wet paper, which is no doubt stronger than the negative electricity acquired by the spiral during combustion.

SECT. III.—*On the Electricity produced by Pressure.*

Experiments of M. Haüy.

The electricity produced by pressure seems to have been first observed by the Abbé Haüy in Iceland spar, which seems to be more susceptible of this species of excitation than any other mineral. If we take into one hand a rhomb of this mineral, holding it by two of its opposite edges, and at the same time lightly touch two of its parallel faces by two fingers of the other hand, and then bring it near to the small needle of the electroscope, it will exhibit *vitreous* electricity. If the two opposite planes, in place of being touched, are pressed between the fingers, a still greater degree of electricity will be developed.

M. Haüy has observed this property of becoming positively electrical by pressure in topaz, especially the variety which is colourless, euclase, arragonite, fluor-spar, and carbonate of lead, all of them substances which are capable of being mechanically cleaved into smooth laminæ. The experiments are always most successful with pure and transparent specimens. Sulphate of lime and sulphate of barytes do not evolve electricity by pressure.

In all the minerals above named which furnish positive electricity by pressure, positive electricity is also produced by friction; and in those substances which develope resinous electricity by pressure, such as a properly shaped piece of elastic bitumen, resinous electricity is also produced by friction. Hence it has been inferred, that in pressing minerals friction is produced, and that the preceding phenomena are only those of excitation by friction.

Experiments of M. Libes.

M. Libes, however, has stated a fact which appears to be hostile to this explanation of the phenomena. He took a metallic disc insulated by a glass handle, and having pressed it on the surface of varnished silk, either when single or several times folded, the *disc* acquired *resinous* and the *silk vitreous* electricity, and the quantity of electricity increased with the pressure. In order to ascertain if friction was a remoter cause of these effects, he set the disc lightly down upon the silk, and rubbing it backwards and forwards so as to produce the effects of friction, the *disc became vitreously and the silk resinously electrified*, a result the very opposite to that which was produced by pressure.

Experiments of M. Becquerel.

This curious subject has been recently examined with much attention and success by M. Becquerel. Having constructed an apparatus for compressing two bodies with a given quantity of pressure, and also an electrical balance of Coulomb, whose platinum torsion wire is sufficiently fine to compare very small electric forces, M. Becquerel sought to determine the phenomena which took place when two bodies were placed under the action of a given pressure and then quickly separated. He found that the excess of electricity acquired by each body was proportional to the pressure as long as it was not great enough to disorganize the body; but if the two bodies are exposed to a certain pressure, and if this pressure is reduced to one half without changing the contact, the effect of the pressure lost subsists during a time, which depends on the degree of conducting power, so that if we immediately withdraw the bodies from compression, each of them will carry off an excess of the opposite electricity greater than that due to the remaining pressure. In place, however, of separating the bodies when the pressure has been diminished, let the pressure taken away be restored, and let this mode of action be several times repeated, the following results will be obtained:

Let a very thin disc of cork be pressed against a plate of Iceland spar with a weight of four kilogrammes; without changing the contact, let this pressure be reduced to one half, and after a minute let the bodies be separated. The tension or intensity of the electricity of each disc is represented by 170. When the separation took place during the whole pressure of four kilogrammes, the intensity would have been 250; and during a pressure of two kilogrammes it would have been 125, or one half. Hence it appears, that in the first case the effect produced by the pressure which was lost still subsisted in part, for it would only have been 125 for two kilogrammes, in place of 170, as given by experiment.

In place of separating the bodies when the pressure has been reduced from four to two kilogrammes, let the pressure of two kilogrammes which was removed be restored, and let us repeat several times the alternate action of simple and double pressures; it will then be found that the disc of each never possesses a greater electrical intensity than 250 relative to the strongest pressure. From these results M. Becquerel draws the following conclusions: first, that the electricity developed by pressure is proportional to the pressure; and, second, that when the molecules have been compressed, the effect of the pressure lost will subsist for some time, even though the contact has not ceased to subsist. This is not the case with conducting bodies, seeing that the two electricities disengaged instantly recombine whenever the pressure ceases.

The following are some of the numerical results obtained by M. Becquerel:

Cork pressed against Iceland spar.

Pressures.	Intensity of Electricity.
1	1·5
2	3·4
3	5·6
4	6

Cork pressed against polished crystals of sulphate of barytes.

1	1·05
2	2·1
3	3·1
4	4·2
6	6·3

Cork pressed against polished quartz.

4..............................3·9

Cork pressed against sulphate of lime.

4..............................1·9

When two insulated discs, one of cork and the other of caoutchouc, are pressed against each other, the cork after pressure is negatively electrical, and the caoutchouc positively electrical. When the cork is pressed against the skin of an orange, the cork is positive and the skin negative.

When cork is pressed against Iceland spar, sulphate of lime, fluor spar, sulphate of barytes, the cork is negative and the minerals positive; but when cork is pressed against kyanite, retinasphaltum, pit-coal, amber, zinc, silver, &c. the cork is positive, and the minerals or metals negative.

When insulated cork is pressed against any part of the animal body free from moisture, the cork receives an excess of negative electricity. The hair and down of animals produce nearly as much electricity by pressure as Iceland spar, but of the opposite kind. Cork pressed lightly against inspissated oil of turpentine is negatively electrified.

When two discs of the same substance, such as skin or amadou, are pressed against each other, the one becomes negative and the other positive.

The electricity thus developed by pressure is lasting. Haüy found it to continue eleven days with Iceland spar. Sulphate of barytes of Royat parts with it instantly unless well insulated; but a well insulated crystal retains it half an hour. The duration of the electricity seems to be inversely as the conducting power. Becquerel supposes the internal surface of the body to be, like the Leyden jar, charged with the opposite electricity; so that dissipation is prevented by the action of the two electricities.

In these phenomena the electricity never appears till the bodies are separated.

When the temperature of any body is raised, it has the greater tendency to acquire negative electricity by friction. In like manner, by heating Iceland spar, it may be made to give *negative* electricity by pressure against cork. If we cut a piece of well-dried cork into two pieces by a very sharp knife, and press the cut surfaces against each other, no electricity is developed; but if one of the pieces is heated slightly near the flame of a candle, and the pressure applied, each surface will, when separated, exhibit opposite electricities. The same is true of two pieces of Iceland spar.

SECT. IV.—*On the Electricity produced by Cleavage and Separation of Parts.*

ctricity separa- n of ts.

It has been long known that electricity is produced during the violent disruption of a body, or by tearing it asunder, or by separating a laminated body, or by breaking a body across, or by crushing it, or even by cutting it into portions.

Mr Bennet observed that when an unannealed glass tear, or Prince Rupert's drop, was put upon a book, it electrified the book negatively. Mr Wilson noticed that if a piece of wood, when dry and warm, is rent asunder, one of the separated surfaces becomes vitreously and the other resinously electrified. When a stick of sealing-wax is broken across, one of the surfaces of fracture is vitreously and the other resinously electrified.

ash from pert's ps.

The electricity developed by the bursting of a Prince Rupert's or unannealed glass drop was found by Sir David Brewster to be accompanied with a flash of light. "These drops," says he, "have three different cleavages, one like the lines of a melon diverging from the apex of the drop, another concentric with the surface of the drop, and another oblique to the axis. Having laid one of these drops upon a table in a dark room, and covered it with a plate of thick glass to prevent any of the fragments from reaching the eye, the drop was burst by breaking off a part of its tail, and the whole of it appeared luminous, so that at the instant of the fracture a quantity of faint light, of the same shape and size of the drop itself, was distinctly visible. The drop which gave this singular result was made of flint-glass, and was the largest that he had ever seen. Every other flint-glass drop produced a distinct electrical light; but in none of them except the large one could he see the luminous shape of the drop. The same light appeared when they were burst under water. The small glass drops made of bottle-glass never exhibited any light at the moment of bursting; but it was almost always visible, in small sparks, in bottle-glass drops of a larger size." The same author observed also a bright electric light when the water-proof cloth manufactured by Charles Mackintosh, Esq. was separated by tearing it into its two component pieces, which are united by a thin film of caoutchouc. He found also that the same light was produced by tearing quickly cotton and other cloths, and by separating the films of mica. The same effects are produced by breaking barley-sugar or sugar-candy.

When the plates of mica, or the laminæ of sulphate of lime, are quickly separated, each of the two plates, when separated, carry off an excess of the opposite electricities, the one being vitreously and the other resinously electrified. If these two plates are again placed together in the position which they occupied previous to their separation, and a slight pressure used to make them adhere, M. Becquerel found that the same phenomena took place as at the instant of their first separation, that is, each plate took the same kind of electricity. This property continued only a few moments, perhaps till the molecules had taken their ordinary state of equilibrium, which is aided by increasing their temperature. The effects above described he found to be more distinct in proportion as the crystal was more heated previous to the cleavage.

Cleavage.

The electrical phenomena produced by cleavage, and by tearing asunder and crushing bodies, differ in degree only from those produced by pressure, as in every case of a separation of parts there must be an approximation of the molecules in one direction. If we press, for example, a piece of caoutchouc in one direction, or draw it out in an opposite direction till it breaks, the effect of both these mechanical actions is an approximation of the molecules in the same direction. Hence the electrical phenomena are nearly the same. The light produced by the collision of hard bodies, or by the separation of the parts of bodies, is no doubt produced by the rapid recombination of the two electricities when developed at the points of pressure.

Cleavage of topazes.

A very curious phenomenon was observed by Sir David Brewster during his numerous experiments on the cleavage of topazes, in which there were cavities containing very highly expansible fluids. His practice was to make the cleavage plane pass through a fluid cavity, and thus to open the cavity and allow its contents to be seen and examined. When this was done, the most expansible of the two fluids flowed from the cavity upon the polished and electrified face of cleavage, and continued to expand and contract itself alternately, now collecting itself into a drop, and then expanding itself into a flat disc. These motions continued till the fluid evaporated; and the effect was no doubt owing to the electricity produced by evaporation, as well as to that produced by cleavage.

Wood shavings.

"The experiments of Mr Wilson on the electricity of wood shavings belong, to a certain extent, to the present section. Having had occasion to work very dry wood that had lain for several hours over a very large fire, he observed the shavings adhering to the tools and to every thing that they came in contact with. When the dry wood was scraped with a piece of window glass, the shavings were always vitreously electrified; but when it was chipped with a knife, the electricity of the chips was vitreous when the wood was hot and the knife not very sharp, but resinous when the wood was perfectly cold. The electricity of the knife was always opposite to that of the chips. The surface of the shaved or chipped wood was seldom electrified, but when it was, the electricity was very feeble, and of the same kind as the weakest of the other two. The wood used in these experiments was beech and cherry tree.

SECT. V.—*On the Electricity of Sifted Powders.*

Sifted powders.

As it has not been determined whether the electricity produced by the falling of sifted powders arises from friction, pressure, or separation of parts, we have thought it best to describe them in a separate section.

Bennet's experiments.

In 1786 Mr Bennet observed that when powdered chalk was blown from a pair of bellows upon the cap of his gold-leaf electrometer, *vitreous* electricity was produced when the cap was *six* inches from the pipe of the bellows, and *resinous* electricity when the distance of the pipe was *three feet.* The vitreous electricity first produced was changed to resinous by breaking the stream of air in the bellows-pipe with a bunch of wire, silk, or feathers, or by removing the pipe so as to make air issue in a wide stream.

When the plate which receives the powders at a distance of *three* inches was moistened or oiled, Mr Bennet found that the electricity was opposite to that produced when the plate was dry.

When powdered chalk fell from one plate to another placed upon the electrometer, resinous electricity was produced; and Mr Bennet obtained the same result when he used red ochre, yellow rosin, coal ashes, black lead, powdered quicklime, powdered sulphur, flowers of sulphur, sand, rust of iron, or iron filings.

When powdered chalk was placed on a metal plate upon the cap of the electrometer, and blown away with the mouth or bellows, it produced permanent vitreous electricity; and the same result is obtained if the chalk is merely blown over the plate, or if a piece of chalk is drawn over a brush placed on the plate.

When chalk or other powders were sifted upon the cap of the electrometer, *resinous* electricity was produced; but when the instrument was placed in a dusty road, and the dust excited by a stick fell upon the cap, *vitreous* electricity was developed.

Cavallo experiments.

M. Cavallo repeated these experiments with some important variations. He insulated a metallic plate upon a glass stand, and having connected it with a cork ball electrometer, he made the dry powder fall from a spoon about six inches above the plate. The electricity communicated to the plate was conveyed to the electrometer, and its nature indicated in the usual manner. When the powder was of a conducting nature, like the amalgam of metals, it was placed in a glass phial, or upon a plate of wax; and sometimes the spoon was insulated, in which case it was always found to possess an electricity opposite to that of the plate. In this manner M. Cavallo obtained the following results:

Powders.	Spoon.	Electricity of Plate.	Strength of Ditto.
Rosin.	Glass or paper.	Negative.[1]	Strong.
Flowers of sulphur.	Ditto.	Negative.	Less strong.
Powdered glass.	Dry paper, warm.	Negative.	Weaker.
Ditto.	Brass.	Positive.	Very weak.
Steel filings.	Glass or paper.	Negative.	
Brass filings.	......	Positive.	
Gunpowder.	Glass.	Negative.	
Fine emery.	Glass.	Negative.	
Amalgam of tin and mercury.	Glass.	Negative.	
Mercury.	Glass.	Positive.	
Soot.	Glass.	Negative.	
Ashes of pit-coal.	Glass.	Negative.	

Experiments of Mr Singer.

The most accurate experiments on the electricity of powders were made by Mr Singer. The following results were obtained by sifting the powders on the cap of a delicate electrometer, through sieves of hair, flannel, or muslin, the sieve being cleaned after every experiment.

The following bodies produced *negative* electricity.

Copper.
Zinc.
Tin.
Iron.
Bismuth.
Nickel.
Black lead.
Lime.
Magnesia.
Barytes.
Strontites.
Alumine.
Silex.
Brown oxide of copper.
White oxide of arsenic.
Red oxide of lead.
Litharge.
White lead.
Red oxide of iron.
Acetate of copper.
Sulphate of copper.
Sulphate of soda.
Phosphate of soda.
Carbonate of soda.
Carbonate of ammonia.
Carbonate of potash.
Carbonate of lime.
Muriate of ammonia.
Common pearl ashes.
Boracic acid.
Benzoic acid.
Oxalic acid.
Citric acid.
Tartaric acid.
Cream of tartar.
Oxymuriate of potash.
Pure potash.
Pure soda.
Rosin.
Sulphur.
Sulphuret of lime.
Starch.
Orpiment.

The following bodies produced *positive* electricity.

Wheat flower.
Oat meal.
Lycopodium.
Quassia.
Powdered cardamum.
Wood charcoal.
Sulphate of potash.
Nitrate of potash.
Acetate of lead.
Oxide of tin.

Mr Singer obtained the following results by bringing an insulated copper plate repeatedly in contact with extensive surfaces of powders spread upon a dry sheet of nome- and aws.

---

[1] Strongly positive when the spoon was insulated.

paper, the copper plate being brought in contact with the condenser after every repetition of the touching, until a sufficient charge was communicated. Very distinct effects were produced with the alkalies by contact with a copper or silver plate, an experiment which had failed in the hands of Sir H. Davy. The pure alkali being broken into small pieces, was exposed in an open phial for a quarter of an hour to a moderate heat not sufficient to fuse the alkali. It was then reduced quickly to a powder in a dry and warm mortar, and distributed instantly over a dry sheet of card paper, which for some time continued to attract moisture from the alkali as rapidly as the alkali absorbed it from the air. The whole operation was performed as rapidly as possible. The following tables contain the substances that gave positive and negative electricity, the copper plate being always electrified oppositely to the powders.

Electricity Positive.

Lime.
Barytes.
Strontites.
Magnesia.
Pure soda.
Pure potash.
Common pearl ashes.
Carbonate of potash.
Carbonate of soda.
Tartaric acid.

Electricity Negative.

Benzoic acid.
Boracic acid.
Oxalic acid.
Citric acid.
Silex.
Alumine.
Carbonate of ammonia.
Sulphur.
Rosin.

From the preceding experiments, which were several times repeated with uniform results, Mr Singer infers that they are unfavourable to the idea of natural electric energy; and he considers the result with sulphur and resin, viz. that the electricity is similar to that produced by their friction, as almost establishing the opinion that the contact of dissimilar bodies is in general the primary source of electrical excitation.

CHAP. III.—ON THE ELECTRICITY PRODUCED BY CHANGE OF FORM.

It has been long ago observed that electricity is developed when bodies change their form, or pass from one state into another. This important fact is exhibited when melted bodies pass from the fluid into the solid state, when fluids are converted into vapour, and when bodies are decomposed by combustion. The phenomena exhibited in these three cases of change of form are very interesting, and will be described in the following sections.

SECT. I.—*On the Electricity developed during the Melting and Cooling of Resinous Bodies.*

ctricity nelted ies.

In our history of electricity we have already given a general account of the experiments by which Mr Stephen Gray discovered a method of developing electricity by the fusion and cooling of resinous bodies. In his nineteenth experiment he formed a large cone of stone sulphur of thirty ounces avoirdupois, by melting the sulphur in a tall glass. The cone began to attract bodies two hours after it was taken out of the glass, and the glass itself exhibited a feeble attractive power. When the sulphur was lifted out of the glass on the following day, its attractive force was very strong, and that of the glass imperceptible. In making these experiments Mr Gray had occasion to place the cone of sulphur on its base between the two windows of his chamber, and to invert the glass over it. Whenever the glass was removed from the cone of sulphur, it exhibited electrical attraction as strongly as the cone, and they both preserved the property for several weeks. The glass, however, at last attracted at a less distance than the sulphur, that is, its attractive force diminished most quickly.

Phenomena and Laws.

Experiment of Wilcke.

These interesting inquiries were resumed by Mr Wilcke of Rostoch, who gave the name of *spontaneous* to the electricity developed by cooled resins. He found that the sulphur acquired a strong electricity whether the glass in which it was fused was insulated or not; but it was always stronger when the vessels were not placed on electrics, and strongest when the glass vessel had a metallic coating. The electricity of the glass was always *positive*, and the sulphur *negative*. The electricity of the sulphur did not appear till it began to cool and contract, and it was a *maximum* at its point of greatest contraction. At this time the electricity of the glass was a *minimum*, having previously reached its *maximum* at the time when the sulphur was shaken out of it. Melted *sealing-wax* becomes *negatively* electrical when poured into *glass*, and *positively* electrical when poured into sulphur. Sealing-wax poured into a vessel of baked wood showed negative, and the wood positive electricity. When sulphur was poured into wood it was negative, but it acquired no electricity whatever when poured into sulphur or rough glass.

Of Æpinus.

Æpinus pursued this subject by melting the sulphur in metallic dishes. The sulphur and the dish showed no electrical signs when they were cooled, but the moment they were separated the electricity of each was very strong, that of the dish being always negative, and that of the sulphur positive. The electricity invariably disappeared when the sulphur was replaced in its dish, and reappeared upon their separation.

If the electricity was abstracted either from the sulphur or from the dish when they were separated, they both exhibited, when re-united, the electricity which had not been taken away, and which always existed *on the surface* of the sulphur.

Electricity of melted chocolate.

Mr Sanders, a maker of chocolate, having observed that the chocolate exhibited electricity during its cooling, communicated the fact to Mr Henley, who having previously repeated the experiments of Mr Gray, resumed the subject. From several experiments made by Mr Sanders under his direction, he found that by heating the chocolate over and over again, the electrical property gradually disappeared; and that it could at any time be restored by the addition of a small quantity of olive oil.

Experiments of Van Marum.

The most elaborate series of experiments on this subject were made by MM. Van Marum and Van Troostwyck. The substances which they employed were sulphur, sealing-wax, gum-lac softened with rosin, rosin, pitch, and wax. These substances were all poured when in a fluid state on the surface of mercury, and all of them, except the sulphur, were electrical after their removal from the metallic surface. These soft solids were next melted in insulated vessels of baked clay, and also in linen and gauze insulated by silk cords; but though Volta's condenser was employed, no proof could be obtained that they had lost any portion of their natural quantity of electricity.

The electricity owing to friction.

In order to verify the suspicion that friction was the source of the electricity generated in the melting and cooling of soft solids, they poured them upon copper, tin, lead, glass, and porcelain, and they invariably found *that they acquired the same kind of electricity as if they had been rubbed by the body on which they were poured.* In confirmation of this opinion they found that the lower surface of each plate was much more strongly electrified than the upper one, and no difference of effect was perceived when the plates were even one inch and a half thick. To obtain still more complete evidence of this conclusion, they melted gum-lac and rosin, and having suspended plates of copper by silk cords, they caused the plates to come in contact with the melted gum, without producing any friction. After the gum was cooled, and the plates again raised, not a trace of electricity could be discovered.

From these results their authors infer that the electricity exhibited in this class of phenomena is not produced either by the separation of the fused substance from the electric on which it is melted, or by the fusion or subsequent cooling of the body, but that it is generated by the friction which the particles of the electric bodies undergo when they disperse themselves over the surfaces of the dishes into which they are poured. The electricity thus produced is masked or counterbalanced by the opposite electricity acquired by the dish, and therefore does not appear till the one is separated from the other.

Electricity of congelation and sublimation.

The electricity produced during the congelation of glacial sulphuric acid and other substances has probably a similar origin; and it is likely that the electrical effects which are observed when calomel fixes itself by sublimation to the upper part of a glass vessel, may belong to the same class of facts. This branch of the subject, however, has been but very imperfectly studied, and will form a fine topic of research for some young and active philosopher.

SECT. II.—*On the Electricity developed during Evaporation and the Extrication of Gases.*

Electricity of evaporation.

Experiments of Lavoisier, Laplace, and Volta.

The development of electricity during the transition of bodies from the solid or fluid state into the state of vapours or gases, was first investigated by MM. Lavoisier and Laplace, with the assistance of M. Volta. Two kinds of apparatus were used in these experiments. In both of them the bodies to be vaporized were insulated by varnished supports of glass; and in those cases where the electricity was quickly disengaged, a common electroscope communicating with the body was used to indicate it, whereas, when the effect was likely to take place continuously, Volta's condenser was employed.

Electricity of chemical action;

When hydrogen gas was rapidly disengaged from iron filings by the action of sulphuric acid, the condenser of Volta afforded a strong spark, and the electricity was negative.

When carbonic acid gas was evolved from powdered chalk, no sensible spark was educed, but the electricity generated was negative.

When nitrous acid diluted with two parts of water was poured upon iron filings placed in six separate vessels, so as to generate nitrous gas, a distinct negative electricity was obtained without a spark.

of combustion;

During the combustion of charcoal in three insulated chafing dishes strong negative electricity was generated; and a spark could easily have been obtained, by increasing the quantity of charcoal.

of evaporation.

Having arranged three insulated furnaces of hammered iron, and made them communicate with the electroscope, water was thrown upon them when heated. In the first experiment the electricity generated was *negative*, and in the other two *positive*; a discrepancy which they ascribed to the cooling which accompanied the evaporation, the positive electricity produced by cooling being supposed to counterbalance the negative effect occasioned by evaporation.

Bennet's experiments.

Mr Bennet, before whom Volta had repeated his experiments in England, published, in the *Phil. Trans.* for 1787, the following interesting facts on the same subject. Having placed a metallic cup with a red-hot coal in it upon the cap of his gold-leaf electrometer, he threw a spoonful of water into the cup. The cup was electrified *negatively*, while the ascending column of vapour exhibited *positive* electricity. When water is poured through an insulated cullender, containing hot coals, the *descending* drops of water are *negatively*, and the *ascending* vapour *positively* electrified; and Mr Bennet regards this as a good illustration of the electricities of fogs and rain. A more simple and certain method of making these experiments consists, according to Mr Bennet, in heating the small end of a long tobacco pipe, and pouring water into the head. The water, being allowed to run through the heated end, is suddenly expanded into steam, and, when projected upon the cap of the electrometer, exhibits signs of electricity. If the pipe, when fixed in a cleft stick, is fixed on one electrometer, while the steam is received upon the cap of another, the two opposite electricities will be simultaneously exhibited. The vapour of alcohol and ether exhibits the same phenomena as that of water, but sulphuric acid and oil generate only smoke, and exhibit no electrical indications.

Experi- ments o Saussur

M. Saussure devoted much attention to this interesting branch of electricity. He confirmed the general results obtained by Volta, Lavoisier, and Laplace, and proved that negative electricity was constantly produced by the evaporation of water. He then determined the degree and kind of electricity produced by evaporation when it was carried on in vessels of different metals, and kept at different temperatures. The apparatus which he employed consisted of a well-baked vessel of clay, four inches in diameter and fifteen lines thick, which was insulated upon a clean and dry goblet of glass. Upon this clay vessel he placed a crucible, or any other dish powerfully heated; and this crucible was made to communicate with the electrometer by means of a wire. Fifty-four grains of distilled water were thrown upon the crucible, and, by means of a time-piece and an electrometer, he observed the duration of the evaporation, and the intensity and character of the electricity.

In his first series of experiments the crucible was of iron; the number of projections of the water varied from 1 to 21, the time of the projection from 0″ to 17′, the duration of the evaporation from $2\frac{1}{2}$″ to 118″, and the degree of electricity from 1 to 18 tenths of a line. In *ten* of these experiments the electricity was *positive*, and in *six negative*. In four of the negative experiments the strongest electricity was 7, 13, 17, and 18 tenths of a line, and in four of the positive experiments the strongest was 3, 3, 5, and 8 tenths; thus showing, as might have been thought, that the weak positive electricity was produced by some secondary cause.

But in repeating the same series of experiments with the same iron crucible, he found very different results. The projections of water varied from 1 to 23, their time from 0′ to 14′ 10″, and the duration of the evaporation from $2\frac{1}{2}$″ to 120″. The electricity was now *always* positive, and its intensity varied from 0 to 30 tenths of a line.

When the experiment was repeated with a *copper crucible* $3\frac{1}{2}$ inches wide at top, 2 inches wide at bottom, 3 inches high, and weighing 57 ounces, the electricity was always *positive*, and its intensity varied from 0 to 33 tenths of a line, the maximum effect taking place when the duration of evaporation was 165″, a mean between the shortest and longest times. In another experiment with the same *copper* crucible, made under the very same circumstances, the electricity was negative at the end of the first projection, but afterwards became positive, and continued so till the experiment was complete.

In the next experiment the crucible was of *pure silver*,

$2\frac{3}{4}$ inches wide at top, $1\frac{1}{2}$ at bottom, $12\frac{1}{2}$ inches high, $1\frac{1}{2}$ line thick, and weighing 16 ounces. At the first trial, when the evaporation was very slow, the electricity, which was always very feeble, was *thrice negative*, and thrice 0. In a second trial it was also negative at first, but it became *positive* afterwards, and then vanished. In a third trial the electricity was stronger and negative. The balls of the electrometer now diverged $3\frac{1}{2}$ lines. It then became *positive*, when the balls diverged $\frac{7}{10}$ths of a line; and at the third projection, when it was still positive, the separation of the balls was so great as *six* lines.

Saussure's next experiment was made with a cup of white *porcelain*, surrounded with sand in a clay crucible. The electricity was *negative*, and the evaporation remarkably rapid. Its intensity varied from 0 to 8 lines. The same results were obtained with different porcelain crucibles.

When *alcohol* and *ether* were substituted for water, and the silver crucible used, the electricity was *negative*. With the former the greatest intensity was 1 line, and with the latter 4·2 lines.

From these experiments Saussure infers, with great hesitation, that the electricity is positive with those bodies which are capable of decomposing water, or of being themselves decomposed by their contact with water; and that it is negative with those which are not decomposed. He ascribed the result with silver to its being adulterated with copper or other oxidable metals. The negative electricity of burning charcoal he supposes to arise from the readiness with which it loses its heat in contact with water.

Saussure was unable to procure electricity either from combustion or by suddenly exploding heaps of gunpowder; and all his attempts failed to develope electricity, *without ebullition*, by evaporation, from large surfaces of wet linen or white iron.

Eperi- mts of Cllo.

M. Cavallo followed Saussure in this inquiry, though he does not seem to have been acquainted with the labours of the Swiss philosopher. He found that evaporation from iron produced negative electricity when the iron was free from rust, but positive when it was very rusty. He found also that white and clear flint glass produced *positive*, while bottle glass evolved *negative* electricity. From these various researches it is not easy to deduce any thing like a general principle. The subject indeed requires to be resumed, and great attention paid to the chemical changes which take place during the progress of the experiments.

SECT. III.—*On the Electricity developed in Flame and Combustion.*

Etricity ome.

We have already seen, in the preceding section, that MM. Lavoisier and Laplace obtained distinct indications of electricity by the combustion of charcoal, and Volta informs us that he never failed to obtain it. Saussure, on the contrary, as has been mentioned, never could develope electricity either by combustion or the explosion of gunpowder; and Sir Humphry Davy equally failed to procure it by the combustion of iron or of charcoal in air or in pure oxygen.

The electrical relations of flame have been subsequently examined by M. Erman of Berlin and Professor Brande. M. Erman concluded, from some experiments, that the insulated flames of *wax, oil, alcohol*, and *hydrogen gas* conduct *only positive* electricity, while the flame of *phosphorus* conducts only *negative* electricity. It was noticed by Mr Cuthbertson that when the flame of a common candle was placed halfway between two equal balls, the one positively and the other negatively electrified, the flame was attracted to the *negative* ball, which consequently became very warm, while the positive ball continued comparatively cold.

Experiments of Brande.

In pursuing this idea Mr Brande placed the flames of various bodies between two insulated brass balls, one of which was insulated positively and the other negatively, and obtained the following results.

Flames, &c. attracted to the Negative Ball.

Olefiant gas.
Sulphuretted hydrogen, slightly.
Arseniated hydrogen.
Flame of hydrogen, weakly.
Sulphuret of carbon.
Potassium in combustion, and its fumes.
Flame of gum benzoin.
Smoke of benzoin.
Charcoal emitted by camphor in combustion.
Resinous bodies in combustion exhibit the same phenomena as charcoal.

Flames attracted to the Positive Ball.

Sulphurous acid vapour.
A *small* flame of phosphuretted hydrogen, slightly.[1]
Fumes of white arsenic, slightly.
Large flame of carbonic oxide.
Vapour of burnt sulphur.[2]
Flame of phosphorus.
Vapour of phosphorus.
Stream of muriatic acid.
Stream of nitrous gas.
Vapour of benzoic acid.

In order to explain these phenomena, Mr Brande supposes, that since some bodies are naturally negative, and others positive, the positive ones will be attracted by the negative ball, and the negative ones by the positive ball.

This conjecture was not confirmed by future observation, and did not lead philosophers to any certain conclusions. The subject, however, was resumed by M. Pouillet, who arrived at a general result, which explains in a satisfactory manner the errors and contradictions of preceding observers.

Experiments of M. Pouillet.

The first point which occupied his attention was the combustion of charcoal; and in his earliest experiments he found with surprise that he could sometimes obtain from it positive and at other times negative electricity, while at other times he could not obtain the slightest electrical indications. In explaining these discrepancies, he supposed that one of the electricities was taken by the charcoal, and the other by the oxygen or carbonic acid; and in order to determine the truth of this supposition he made the following arrangement. Having taken a cylinder of charcoal, he placed it vertically six or eight centimeters below a plate of brass which rests upon one of the discs of the condenser. The charcoal having a communication with the ground, was lighted at its upper end without the fire reaching the lateral surface, and there arose a column of carbonic acid, which struck the plate of brass, and in a few seconds charged the condenser. The electricity which the condenser received from the carbonic acid was *always positive*, whereas Lavoisier, Laplace, and Volta made the electricity *negative*. When the char-

Combustion of charcoal.

---

[1] When the flame was *large* it was equally attracted by both balls.

[2] The direction of the flame could not be determined.

coal was held nearly horizontally, so that the carbonic acid which was generated could rise only by ascending along the base of the charcoal, which was now vertical, *no sensible effect was obtained;* and when the lateral as well as the upper surface of the charcoal, placed vertically, was lighted, an uncertain result was obtained.

In order to determine the electricity of the charcoal itself, M. Pouillet places the base of the cylinder upon the disc of the condenser; and after lighting the upper end of it, and keeping up the fire by a gentle blast of air, the condenser was charged, and showed that the electricity taken by the charcoal was negative. When the charcoal burnt on all its surface, or when it touched the condenser only in a few points, no electrical effects were observed. In the last of these cases a small quantity of electricity only can pass by a small number of points, and in the first case the positive electricity of the ascending carbonic acid was recombined with the negative electricity. In order to produce intense and rapid electrical effects, several cylinders of charcoal, of the same height, should be placed on their ends, and near each other, upon a sufficiently large plate of brass; and when all the cylinders are made to burn at their upper ends, and their united columns of carbonic acid received by another brass plate communicating with the condenser, and raised a few inches, or even a foot, above it, a strong charge of *positive* electricity will in a few seconds be communicated to the brass plate. When the electricity of the charcoal is required, we have only to unite the condenser to the brass plate upon which the burning cylinders are placed, and in a few seconds the condenser will be abundantly charged with *negative* electricity.

When the combustion is maintained by a current of oxygen, the electricity is not only much more intense, but is much more quickly developed; and the gold leaves of the condenser separate to their maximum divergency in an instant. The first point, however, to be attended to in every form of the experiment, is to burn only the upper horizontal surface, so that the carbonic acid forms and ascends in a moment, and without touching any other body till it deposits its electricity on the brass plate. So essential is this condition, that if we burn even a deep cavity on the circumference of a vertical cylinder of charcoal, and do this even with a jet of oxygen, the electrical indications are sometimes positive and sometimes negative, just as the electricity of the gas or the charcoal predominates.

Experiments of Pouillet.

M. Pouillet next entered upon the more arduous investigation of determining whether or not electricity is produced by change of condition or chemical affinity. Volta had supposed that carbon, in becoming gaseous, absorbed the positive and left to the remaining solid parts the *negative* electricity which we find in them. M. Pouillet, on the contrary, supposed that if electricity is disengaged from two elements which combine, positive electricity would be given out by the one and negative by the other; and that when these elements separate, each of them required to take up the fluid which they had lost.

Combustion of hydrogen.

By forming combinations unaccompanied by changes of condition, M. Pouillet resolved this question. He first tried that of oxygen and hydrogen. The flame of hydrogen, like charcoal, gave electricity, sometimes strong and sometimes feeble, sometimes *positive* and sometimes negative; and it was some time before he discovered the cause of these discrepancies. That the gases are not very good conductors of electricity, he found by the following very curious experiment. Having set a very small spirit-lamp upon a common electroscope, and about five or six feet above it a feebly charged body, such as a stick of electrified rosin or a plate of glass, he observed that the gold leaves diverged greatly, though the same charged body could produce no divergence if held even so near as an inch to the electroscope without flame. This apparatus enabled our author to discover the smallest trace of electricity. If we turn the plate of an electrifying machine, the air of the room is electrified; and the flame which ascends in that air is charged at the moment with electricity of the same name. A pile in action electrifies the air in the same manner, as the flame of the electroscope proves. A charcoal fire, or even a lighted candle, developes carbonic acid electrified positively, which is shown also by the electroscope. The atmospheric air, in short, is always electrified; and if it enters a room by any opening, it will preserve itself in an electrified state so long as to affect the results of experiments on small quantities of electricity.

These causes of error being excluded, M. Pouillet repeated his experiments on the combustion of hydrogen. The gas was emitted from a glass tube, and the flame, which was vertical, was about three inches long and four or five lines broad. The brass plate was now set aside, and the electricity conducted to the condenser by a platina wire, whose end is coiled into a spiral. The spire is vertical, and the circumvolutions are sometimes so large as to surround the flame without touching it, and sometimes so small as to be completely enveloped in the interior of the flame. When we approach this flame from the exterior outline of the spire, and keep it ten millimeters distant, we obtain indications of positive electricity. As the distance of the flame diminishes, the electricity becomes more and more intense; but when the flame touches the spire, the electricity becomes weak, and its nature uncertain. The same thing is observed when the flame passes to the interior of the spire, and in the direction of its own axis. Hence there exists round the apparent flame of the hydrogen a sort of atmosphere, more than ten millimeters in thickness, charged with positive electricity. Positive electricity being thus developed in the combustion of hydrogen, Pouillet tried to discover the negative electricity which must have been set free. He placed a small spiral in the centre of the flame, and when it was enveloped on all sides, negative electricity was collected by the condenser. If we plunge the spire half way into the bright part of the flame, no electricity is manifested. Hence it follows that the inside and outside of the flame are in opposite electrical states, the former being negative and the latter positive, and that there is an intermediate layer of the flame where the electricity disappears. On these facts M. Pouillet thus reasons. In the thickness of the exterior atmosphere of the flame, when the positive electricity appears, the combination of oxygen and hydrogen is not effected, for the hydrogen cannot arrive there. The electricity is therefore communicated, and it must come from the oxygen which predominates on the outside, and which envelopes in some measure all the jet of hydrogen. This combined oxygen must therefore disengage positive electricity, which communicates itself to the neighbouring strata of air sufficiently heated to conduct it. In like manner the hydrogen predominates in the interior of the flame, and the negative electricity must be disengaged from the hydrogen which burns, and which it communicates to the excess of uncombined hydrogen. If this view is correct, it is probable that, at a certain distance above the flame, the two opposite electricities ought no longer to appear, as they must have combined; and this is proved to be the case by the fruitless attempt to collect electricity at a distance sufficiently great above the vertical flame. At the distance, however, of a few inches, other phenomena appear. The two electrical fluids appear there in the same quantity, but they are not recombined; for if we present a solder-

Electri of flam

ed plate of zinc and copper, the zinc will attract the positive and the copper the negative electricity.

When the hydrogen issues from a metallic in place of a glass tube, and a communication is made with the condenser and not with the ground, the metal tube, which touches the hydrogen without touching the flame, always takes the negative electricity; and, on the contrary, if the tube communicates only with the ground, it loses in this manner the negative electricity which it had before taken to the condenser, and the product of the combustion preserves an excess of positive electricity.

In pursuing this inquiry in a similar manner, M. Pouillet found that the flames of alcohol, ether, wax, the oils, fatty substances, and several vegetable bodies, present exactly the same phenomenon as the flame of hydrogen. He observed, however, that the particles of charcoal which float in all these flames, and which, according to Sir H. Davy, give them the lustre with which they burn, render them also more fitted to manifest negative electricity. From these results M. Pouillet has deduced the general conclusion, *that in combustion the molecules of oxygen which combine disengage positive electricity, which may be communicated to the neighbouring molecules not yet combined; and that the combustible body, on the contrary, disengages negative electricity, which can, in like manner, be communicated to all the neighbouring combustible parts.*

Eri- mts of M Bec- qel.

The experiments of M. Pouillet were repeated by M. Becquerel in 1827, on the flames of hydrogen gas or alcohol; but he commenced them with some reserve, for, as they were made by means of platina wires plunged in the flame, he supposed that the phenomena were not only owing to the electricity disengaged during combustion, but also to some property which the metals acquired at a certain temperature. The following is the general fact, without entering into any of the details of his experiments: A platinum wire communicates by one end, through the intermedium of a band of wet paper, with one of the plates of a condenser, the other end being plunged in one of the envelopes of a flame produced by the combustion of alcohol, contained in a vessel of copper, which the observer holds in his hand. The end of the wire may even be placed without the flame, provided it is so near it as to become red hot. The wire soon takes a considerable excess of negative electricity, which ought not to be ascribed entirely to that which the alcohol carries off during combustion. In order to prove this, let us resume the last experiment but one. As soon as the end of the platinum wire attains a red heat, let us withdraw the lamp, and touch this end of the wire with a band of wet paper, or rather with the end of a tube of hot glass; the effect is the same as when the wire touched the flame, or was at a small distance from it. It is very probable that the disengagement of the electricity is due, in this last case, in part to the difference of temperature between the two ends of the wire, and that the flame has carried off the positive electricity of the wire, or the band of wet paper, as the hot glass tube had done. This opinion is confirmed by the circumstance that the effect is the same whether we bring the wire to a red heat in the interior or in the exterior of the flame, neither of which possesses the same kind of electricity. Notwithstanding this result, M. Becquerel still admits, that during the combustion of alcohol and hydrogen, the exterior envelope of the flame is charged with positive electricity.

M. Becquerel has endeavoured to explain the curious fact discovered by M. Erman, and already referred to. Having placed upon an electroscope a lamp without flame, whose platinum wire was kept at a red heat by the burning vapour of the alcohol, he held above the spiral the negative pole of a dry pile, and the two gold leaves instantly diverged. He next held the positive pole above the spiral, but there was now no divergence of the leaves. Hence the platinum wire afforded a passage only to the negative electricity. The contrary effect took place when the electricity passed from an incandescent wire to another which was not so; and hence M. Erman found that the incandescent wire was reciprocally a conductor and insulator of each fluid.

In order to show that this conclusion is incorrect, M. Becquerel presented successively to a red-hot platinum wire the two poles of a dry pile, and it conducted equally well both kinds of electricity. Besides, as he remarks, it appears, from our knowledge of the electrical effects produced in gaseous combustion, and by increase of temperature, that part of the air which surrounds the red-hot wire of the lamp without flame ought to be in a positive state of electricity, and the wire which is in the middle of the alcoholic vapour in a negative state. Moreover, it is evident, from what has been already stated, that the part of the wire which is red hot ought easily to yield positive electricity to contiguous bodies. This being admitted, when we present to this wire the negative pole of a dry pile, there are two reasons why the negative electricity should neutralize both the positive electricity of the surrounding air, and that of the red-hot wire which tends to escape from it. The negative electricity of the wire then becoming free, manifests its action upon the electroscope. In repeating the experiment in an inverse manner, that is, by causing each of the two electricities to escape successively by the red-hot wire, as this last tends to be negative, it neutralizes the positive electricity which arises, and sets free that of the surrounding air and of the red-hot end of the wire. It is not therefore necessary to have recourse to a reciprocity of insulating and conducting action in the red-hot wire in order to explain the phenomenon, for the fact admits of an easy explanation on the properties above explained.

SECT. IV.—*On the Electricity of the Solar Rays.*

Electricity of the solar rays.

Our readers are no doubt aware that Dr Morrichini and others succeeded in magnetising needles by the action of the blue rays in the solar spectrum. Other philosophers have failed, even in good climates, in obtaining decided indications of magnetism, so that accurate researches are still wanting to remove this opprobrium from our experimental physics. The very same observations are applicable to the development of electricity by the influence of solar light; but still it is necessary, in a work like this, that we should give some account of the experiments from which this electrical action has been inferred.

Experiments of Barlocci;

In a memoir on the influence of solar light in the production of electric and magnetic phenomena, Professor Saverio Barlocci of Rome relates the following experiments: Having formed the prismatic spectrum by the solar rays, he caused the red rays and the violet rays to fall upon two discs of blackened copper, each of which was attached to a copper wire. Two copper nuts sliding upon a vertical glass rod, and to which the two wires were fixed, allowed the discs to be brought near each other or separated at pleasure. A prepared frog was then suspended by the body to the upper wire, and the legs were placed upon the lower one. The red rays being made to fall on one disc, and the violet on the other, the extreme parts of the two wires were brought into contact, and distinct signs of contraction were observed in the frog.

of Matteucci.

M. Matteucci of Forli has more recently investigated the same subject. Having exposed to the sun a delicate condensing electrometer of gold leaf, he soon perceived the leaves diverge and open themselves on that side of the glass which was directly exposed to the solar action, as if they had been attracted by it. Hence he was led to suspect that glass thus exposed was electrified; and in order to ascertain this, he placed some plates of it in the sun, and having in a few minutes touched them in different places with the ball electrometer, a perceptible divergence took place. This divergence was much more apparent when he touched the plates even lightly with a flat surface, as the effects of the friction did not afford a doubtful result.

Having inferred from these results that the solar rays had the power of developing electricity in glass, M. Matteucci endeavoured to ascertain whether this was owing to the existence of electricity in the rays themselves, or to the increased temperature of the glass. He therefore heated a plate of glass repeatedly, and having tried it with the electrometer, he never could discover in it any signs of electrical action. M. Matteucci likewise observed that the glass plate exposed to the rays of the sun never became electric if placed beneath another glass plate, or if the face of the sun was obscured by a cloud.

Experiments of Dr Faraday.

Dr Faraday likewise made experiments on the solar spectrum, in the same manner as that used by M. Barlocci, with the exception that he used a very delicate galvanometer in place of a frog; but, to use his own words, "no electricity could be obtained by means of an English sun."

M. Delarive has still more recently (*Bibl. Univers.* July 1833, p. 326) stated that, after taking every precaution to avoid the action of extraneous causes, he could not discover in the solar rays the slightest trace of electricity.

SECT. V.—*On the Electricity produced by Vegetables.*

Electricity of vegetation.

Mr Read seems to be the only author who, previous to the researches of M. Pouillet, had made any distinct statement respecting the electricity of vegetable bodies. He had concluded, from several experiments, that vegetable putrefaction is always electrified negatively, while the surrounding atmosphere is electrified positively. It is to M. Pouillet, however, that we owe all our knowledge on this subject, and in the present section we shall communicate to our readers a general abstract of his researches.

Researches of M. Pouillet.

That the various parts of plants act upon atmospheric air is well known. At the expense of the oxygen they sometimes form a large quantity of carbonic acid gas, which disengages itself insensibly; and sometimes they exhale pure oxygen, proceeding from some combination which goes on in the interior of the plant.

As carbonic acid gas is electrified vitreously at the moment of its formation, from charcoal in combustion, M. Pouillet conceived that a considerable quantity of electricity ought to be produced during the exhalation of this acid from growing plants. This idea was soon confirmed by experiment, and M. Pouillet was led to the important conclusion that vegetation is an abundant source of electricity, and is therefore a powerful cause in the generation of the electricity of the atmosphere.

He took twelve capsules of glass, about nine inches in diameter, and coated them externally, but only to a distance of one or two inches towards the edge, with a film of gum-lac varnish. They were then arranged in two rows at the side of each other, either on a table of very dry wood, or on a table which was itself varnished with gum-lac. When they were filled with vegetable mould, they were made to communicate with each other by metallic wires, which went from the interior of the one to the interior of the other, passing over the edges of the capsules. In this manner all the insides of the twelve capsules, and the mould which they held, formed only one conducting body. If electricity is communicated to such a system, it will be distributed over the twelve capsules, and will remain there, as it cannot pass into the ground, nor even into the exterior surfaces of the capsules, on account of the film of gum-lac round their edges. The upper plate of a condenser is now put in communication with one of the capsules by means of a brass wire, and its lower plate with the ground by the same means; and these communications are so made that they may be kept up even for several days. The grain of which we wish to study the effects is then sown in the earth in the capsules, and from this moment the laboratory must be closely shut, and neither fire nor light, nor any electrical body, admitted.

This experiment was made during the dry north and east winds of the month of March. During the two first days the surface of the mould was dried up, and the grains swelled; the germ projected about a line out of its envelope, without, however, appearing above the thin stratum of earth which covered the grain; and the condenser, after several trials, gave no signs of electricity. On the third day the germs had come out of the mould, and began to raise their points towards the window, which had no shutters. Upon now trying the condenser, M. Pouillet saw a divergence in the gold leaves, and he found the electricity to be negative in the capsules, and positive in the gases which were disengaged. Hence M. Pouillet infers that the rapid action which the rising germ exercises on the oxygen of the air disengages electricity.

The apparatus was then put into its usual state, and after the lapse of some hours the action of the germ again charged it with electricity. Upon visiting the apparatus next morning, M. Pouillet found that it gave a very strong electric charge, and the electricity was of the same kind as before. During the next eight days the vegetation continued active, and at all times of observation, both during the day and night, the condenser exhibited more or less electricity, according to the time that had elapsed. After twelve hours the divergence of the gold leaves was more than an inch, and the electricity of the earth in the capsules was always *negative*. Damp weather followed, and it was then impossible to collect the least quantity of electricity.

M. Pouillet's next experiment was to make two vegetations of corn, two of cresses, one of gillyflower, and one of lucerne; but he was obliged to maintain in his laboratory an artificial dryness, by spreading in a very large apartment several bushels of quicklime broken into very small fragments, and he also distributed in porcelain saucers several kilogrammes of muriate of lime, and placed them near the capsules. The condenser now exhibited a more intense electricity than before, and in each operation the development of the vegetable action, and that of the accompanying electrical phenomena, were observed during ten or twelve days. So rapid was the development of electricity, that after the three or four first days of vegetation, if the condenser was put into the natural state after one observation, and it was then replaced for experiment only during *one second*, it was then found to be charged with electricity. "But," as M. Pouillet observes, "it is evident that, during one second, the weight of oxygen which combines and disengages during a languid vegetation, of only three or four square feet, is a weight so feeble, and a fraction of a millegramme so imperceptible, that the electricity which it disengages is not sensible to the condenser. One is apt to fear, after this, that the electricity has another source, and that it can only be developed by some foreign cause; but upon reflection we see that the earth of the capsules is so dry that it becomes an imperfect conductor, that the electricity is retained, and that it is it which charges the condenser. To be certain of this, it is sufficient to place successively in contact with the condenser, one, two, three, or a greater number of capsules, and we shall see the charge increase in proportion as the number increases; in short, it is sufficient to place them in communication with the ground for a long time, when they will no longer give a charge to the condenser, and it will be many hours after that before they communicate a sensible electricity. It is without doubt this imperfect conductibility of the dried earth which has rendered it impossible for me to observe until now any electrical charges during the periods of day or night, although I took every precaution to observe it, presuming that if the disengagement of carbonic acid produce resinous electricity in the ground, the disengagement of oxygen ought, on the contrary, to produce vitreous electricity.

"It is perhaps the same cause which has given birth to another phenomenon, which I have not yet studied sufficiently to give an exact account of it. It happened twice that the electric signs had ceased during two or three days, and that they were then presented in opposite directions, that is to say, the capsules had exhibited vitreous electricity, and had continued to exhibit it, with a very weak intensity, during the rest of the vegetation."

Sect. V.—*On the Electricity of Living Animals.*

tricity ving als.

When we consider the structure of organized bodies endued with life and motion, we should naturally expect, from the phenomena described in the preceding section, that electricity would be developed in the chemical processes and changes which are incessantly taking place. During the processes of digestion and assimilation, for example, in which both solid and fluid bodies are changing their form, and in the process of respiration, in which the atmospheric air is decomposed, electricity cannot fail to be developed in greater or less intensity.

Another source of electricity in animal bodies is no doubt the friction between the clothing and the skin; and the electricity thus generated will be more or less intense, according to the state of the atmosphere, the nature of the clothes, and the constitution and habits of the individual.

But, independent of the electrical phenomena which arise from these causes, we find in certain fishes a regular system of electrical organs, by which they either defend themselves from the attacks of their enemies, or seize the prey which nature has provided for their use. The curious phenomena which have been observed relative to these subjects will be described under separate heads.

Art. 1. *On the Electricity of the Human Body.*

tricity e hu- body.

Long before electricity had become a science, electrical phenomena had been distinctly observed. Cardan relates, that sparks were emitted from the hair of a Carmelite monk, whenever it was stroked backwards; and Faber mentions a young woman from whose hair sparks of fire always fell when it was combed. Cassandra Buri, a Veronese lady, often terrified her maid-servants by brilliant sparks, and a crackling noise, which were emitted when her body was rubbed, or even touched slightly, by a linen cloth. Antonio Ciampi, a bookseller at Pisa, emitted sparks from his back and arms with a crackling noise, whenever he pulled off a narrow shirt and a piece of cloth which he wore upon his breast.

Gesner relates, that in Germany, where heated stoves prevailed, it was exceedingly common to observe crackling flames issue from the shirts of persons who had been previously warming themselves at a stove.

The experiments of Mr Symmer on the electricity of silk stockings that had been worn, which we have already detailed, correspond with the preceding facts; and there are few individuals who have not observed similar electrical phenomena in changing different parts of their dress.

Experiments of Saussure;

That the electrical effects exhibited in the human body are, generally speaking, produced by the friction of the clothes against the skin, has been proved by the experiments of Saussure, Landriani, the Abbé Bertholon, and M. Volta. M. Saussure examined the electricity of his own body by means of Volta's electrometer and a condenser, and he never could discover any electricity in it when he was perfectly naked, when his clothes were cold, or when he was in a state of perspiration. In other states of his body and dress, the electricity which did manifest itself was sometimes positive and at other times negative, without any apparent cause for these variations. When he bent his body forwards, and raised himself suddenly, the balls of the electrometer diverged to a considerable distance, and then collapsed; but if he drew away his hand when the balls were thus divergent, they continued in this state of divergency, and exhibited positive electricity. Saussure observed also that the motion produced by respiration is of itself sufficient to produce a small quantity of electricity; for when he remained on the insulating stool in a state of the most perfect repose that a living being could observe, distinct indications of electricity were manifested when he laid his hand for some time on one of Volta's condensers.

of Hemmer.

The most complete series of experiments on the electricity of the human body were made by M. J. J. Hemmer of Manheim. He insulated himself upon a board supported by glass feet, and then touched for about half a minute a condenser. The condenser was then applied to Saussure's improved electrometer, and, by means of a glass tube excited by woollen cloth, he examined the nature of the electricity. The following are the results of experiments which he made upon himself on the 21st of February 1786, and which he has repeated upon persons in every state of body and mind, and under every variety of dress and temperature.

1. The electricity of the human body is common to all men. It was found in thirty persons of all ages and sexes; but it varied in strength in different individuals, and was positive in some and negative in others.

2. The intensity and character of the electricity often varies in the same person. In 2422 experiments M. Hemmer found it 1252 times positive, 771 times negative, and 399 times imperceptible. Out of 94 experiments made upon his maid-servant, it was 17 times positive, 33 times negative, and 44 times imperceptible.

3. The electricity of the body is naturally positive; for when it is subject to no violent exertion this is always its character. Out of 356 experiments made upon himself when sitting at rest, and when the natural heat of his body was not disturbed, his electricity was 322 times positive, 14 times negative, and 10 times imperceptible.

4. The natural positive electricity of the body is changed into negative by cold, or is greatly diminished. Out of 62 experiments made upon himself when he came from a temperature of 32° of Fahrenheit, his electricity was 38 times negative, 15 times positive, and 7 times imperceptible.

5. The natural positive electricity of the body is changed into negative by lassitude. Out of 16 times that he walked backwards and forwards in his apartment, or was otherwise employed, he found the electricity only

Phenomena and Laws.

once weakly positive, 10 times negative, and 5 times imperceptible. In 32 experiments made when he was standing at rest, the electricity was 2 times weakly positive and 30 times imperceptible.

6. The natural positive electricity of the body is changed into negative by sudden, speedy, and violent motion.

It is obvious from these experiments, that the human body possesses no electrical organs over which the will exercises any control, and that its electricity depends on the chemical and physical changes which are taking place either in its interior or upon its surface.

It has been supposed that the remarkable phenomena of spontaneous combustion in the human body are somehow or other connected with its electrical state; but we possess no accurate data by which the truth of this opinion can be tried.

Art. 2. *On the Electricity of the Raia Torpedo.*

Electricity of the torpedo.

The remarkable property of giving an electrical shock possessed by this fish was known in the time of Aristotle and Pliny, and has been distinctly described by Appian. Redi, Reaumur, Kæmpfer, and Bancroft, successively described the phenomena which it exhibited; and Lorenzini, so early as 1678, published good engravings of the electrical organs of the torpedo.

Experiments of Walsh.

The first person, however, who made accurate experiments on the torpedo was Mr Walsh. He confirmed the remarkable observation of Kæmpfer, that the shock could be evaded if the person who touched the animal held in his breath at the time. Mr Walsh made two series of experiments on this fish, one when it was placed in the air, and the other in the water. In the first series he placed a living torpedo upon a table covered with a wet napkin, round which stood five persons who were insulated. Having suspended from the ceiling by strings two brass wires, each thirteen feet long, one of them was made to communicate by one extremity with the wet napkin, while its other extremity was plunged in a basin of water placed upon a second table, on which other four basins of water stood. The first of the five insulated persons plunged a finger of one hand in the basin in which the above-mentioned wire was placed, and a finger of the other hand into the second basin. The second person put a finger of one hand in this second basin, and a finger of the other in a third basin, and so on till the five persons formed a communication with each other by the water in the basins. The end of the second wire was plunged in the last basin, and Mr Walsh having taken the other end of this wire in his hand, touched the back of the torpedo, when all the five persons experienced a shock which differed only in force from that of the Leyden jar. The shock seldom extended beyond the touching finger, and out of 200 only one reached above the elbow. When the torpedo was insulated, it gave forty or fifty shocks to insulated persons, without any diminution of its force. Mr Walsh found that the shock was communicable through iron wires and other conductors, but not through air, glass, and other electrics; and he was never able either to produce a shock, or move the pith balls of an electrometer. In the series of experiments in water, Mr Walsh held a large and powerful torpedo in both hands by its electric organs, and after plunging it about a foot under water, he raised it suddenly to the same height in air. The instant the lower surface of the fish touched the water in descending, he received a violent shock, and the instant the same surface quitted the water in ascending, he experienced a still more violent shock. A writhing of the fish accompanied both these shocks, particularly the last. The intensity of the shock under water was scarcely one fourth of that at the surface, and not much more than one fourth of those given in the air. The number of shocks in a minute was about twenty, generally two and always one when he was wholly in the air, and sometimes two when he was below water. When the finger of one hand touched the upper part, and the thumb of the same hand the lower part, of a single organ, the shock was twice as great as when it passed through the arms, and Mr Walsh concluded that the two sides of the fish are in opposite electrical states.

Phenor na an Laws

Experi- ments o Ingen- housz;

Dr Ingenhousz, who repeated and confirmed these experiments, says that the sensation of the shocks is the same as if a great number of very small electrical bottles were discharged very quickly through his hand. M. Spallanzani found the shocks strongest when the fish was laid upon a plate of glass. When the animal was dying the shocks were not given at intervals, but resembled a continual battery of small shocks. The battery continued seven minutes, and in this time he experienced 316 shocks. Spallanzani also found that the fœtus gave perceptible shocks like the full-grown fish.

of Hum boldt an Gay Lu sac.

In the year 1805, MM. Humboldt and Gay Lussac examined the properties of the torpedo at Naples, but they do not seem to have added much to the observations made by Mr Walsh. They found that a person accustomed to electric shocks could with some difficulty support the shock of a vigorous torpedo fourteen inches long; that before each shock there is a convulsive movement of the pectoral fins; that the animal must be irritated previous to the shock; that the shock may be felt when a single finger is applied to a single surface of the electric organ; that an insulated person will not receive a shock if he touches the fish with a key or any other conducting body; and that the least injury done to the brain of the fish prevents its electrical action.

Electri organs.

At the request of Mr Walsh, the celebrated anatomist Dr Hunter examined the electrical organs of a torpedo about eighteen inches long, twelve broad, and two thick. These organs are placed on each side of the cranium and gills, reaching from thence to the semicircular cartilages of each great fin, and extending in length from the anterior extremity of the animal to the transverse cartilage which divides the thorax from the abdomen. Within these limits the organs occupy all the space between the skin of the upper and outer surfaces. This description will be understood from fig. 1 of Plate CCXIII., which represents a female torpedo, the skin B having been flayed from the under surface of the fish, to show the electric organs A. The nostrils, in the form of a crescent, are shown at *c*, and the mouth, having a crescent form, opposite to the nostrils, at *d*. The mouth is furnished with several rows of small hooked teeth. The bronchial apertures are shown at E, five being on each side; F is the place of the heart, *gggg* the place of the anterior transverse cartilages, *hh* the exterior margin of the great lateral fin, *i* its inner margin on the confines of the electrical organ, *l* the abdomen, *mmm* the place of the posterior transverse cartilage, which is single, united with the spine, and sustains the smaller lateral fins *nnnn* on each side; O is the anus, and P the fin of the tail.

Plate CCXII fig. 1.

Each organ is about five inches long, and about three inches broad at the anterior end, and half an inch at the posterior extremity. Each organ consists wholly of perpendicular columns reaching from the upper to the under surface of the body, and varying in their lengths according to the thickness of the parts of the body where they are placed. The longest column is about one and a half inch, the shortest about one fourth of an inch, and their diameter about two tenths of an inch. The figures of the columns are irregular hexagons or pentagons, and some-

Ph ome- and ws.

times have the appearance of being quadrangular or cylindrical. The number of columns in the fish examined by Dr Hunter was 470 in each organ; but in a very large fish four and a half feet long, and weighing seventy-three pounds, the number was 1182 in each organ. The number of partitions in a column one inch long was 150. The nerves inserted into each electric organ arise by three very large trunks from the lateral and posterior part of the brain; and when they have entered the organs they ramify in every direction between the columns, and send in small branches on each partition, where they are lost. Dr Hunter remarks that there is no part of any animal with which he is acquainted, however strong and constant its natural action, which has so great a proportion of nerves; and he hence concludes that, if it be probable that these nerves are not necessary for the purposes of sensation or action, they are subservient to the formation, collection, or management of the electric fluid.

M. Geoffroy de St Hilaire has more recently examined the torpedo. He analysed the fluid in the cells of the hexagonal columns, and found it to consist of albumen and gelatine; and, what is very curious, he discovered organs analogous to those of the torpedo in other species of the same genus Raia, which do not possess any electrical power.

erva- ti and eri- nts of Todd.

Some useful observations were made upon the torpedo of the Cape of Good Hope in 1812 by Mr John T. Todd. The torpedos of this locality are never more than eight, nor less than five inches in length, and never more than five, nor less than three and a half inches in breadth. The columns of their electrical organs were larger and less numerous in proportion than those described by Hunter, and they appeared to be of a cylindrical form. The shocks of these torpedos were never sensible above the shoulder, and seldom above the elbow joint. The electrical discharge was generally accompanied by an evident muscular action, as shown by an apparent swelling of the superior surface of the electrical organs. From a great variety of experiments, which we have not room to enumerate, Mr Todd drew the following conclusions:

1. That the electrical discharge is a vital action dependent on the life of the animal.
2. That the action of the electrical organ is entirely voluntary.
3. That frequent action of them is injurious to its life, and, if continued, deprives the animal of it.
4. That when the nerves and the organs are cut, the torpedo loses the power of giving a shock, though it appears more vivacious, and lives longer, than those in which this change has not been produced, and in which the electrical power is exerted.
5. That the possession of one organ only is sufficient to produce the shock.
6. That the perfect state of all the nerves of the electrical organs is not necessary to the production of the shock.
7. That (as was shown by Dr Hunter) a more intimate relation exists between the nervous system and electrical organs of the torpedo, both as to structure and functions, than between the same and any organs of any animal with which we are acquainted.

In 1816 Mr Todd made another series of experiments at La Rochelle, principally with the view of determining whether the torpedo possessed any voluntary power over the electrical organs, either in exciting or interrupting their action, except through the nerves of these organs. Shocks were given by the torpedo even when one half of each electrical organ was removed; and also when an incision was made extending round the circumference of both organs, so as to leave no attachment between these organs and the animal except the nerves. When the large lateral cartilages were removed, and a large portion of the surfaces of the electrical organs denuded, two distinct shocks were received; but the fish being much injured, soon died. During these experiments, Mr Todd observed how powerfully the action of the electrical organs was excited by the cutting of the scalpel; and on one occasion, when he pressed on the electrical organ with his left hand, and held the scalpel wet in the other while cutting the electrical organ, he received a distinct shock in the right hand through the scalpel. He observed also that all the nerves of the electrical organs arise from the medulla oblongata, notwithstanding the long course which three of them are obliged to follow.

Phenomena and Laws.

Mr Todd informs us that the torpedo called *la tremble*, which occurs on the coast between the Loire and the Garonne, is eaten by the poorer inhabitants, who carefully avoid the electrical organs, which are supposed to possess some disagreeable properties.

Observations and experiments of Sir H. Davy;

In 1814 and 1815, when Sir H. Davy was on the shores of the Mediterranean, he was desirous of ascertaining whether or not the electricity of the torpedo possessed the chemical and magnetic powers of that agent. In both these trials he could neither decompose water, nor influence a highly delicate magnetic electrometer; and he seems disposed to infer that there is a stronger analogy between the common and animal electricity than between common and Voltaic electricity, and that it is probable that animal electricity will be found to be of a distinctive and peculiar kind.

of Dr John Davy.

This eminent chemist intended to pursue these inquiries, but his ill health prevented him; and in his latest illness he requested his brother, Dr John Davy, to carry on the investigation. Dr Davy accordingly pursued the inquiry at Malta, and succeeded in obtaining several important results. He placed a needle perfectly free from magnetism within a fine copper spiral wire one and a half inch long and one tenth of an inch in diameter, containing about 180 convolutions, and weighing about four and a half grains. By the electricity of a torpedo about six inches long, he succeeded in communicating distinct magnetism to this needle; and he repeated the experiment with the same success with fishes of different sizes. Dr Davy likewise succeeded in throwing into violent motion the needle of a magnetic multiplier. With every fish he tried he obtained decisive results, and he met with no instance of a fish which had the power of magnetising a needle in the spiral wire failing to move the needle in the multiplier, though he met with more than one example of a fish whose electricity was equal to the latter effect and not to the former. Dr Davy, however, failed in obtaining any igniting power, or the faintest spark, by means of the torpedo. He also found that air was not impermeable to the electricity of the torpedo; but he never could exhibit any influence on the electrometer, or any indications of attraction and repulsion in air.

Chemical and magnetical effects.

Dr Davy's experiments on the chemical agency of this species of electricity were highly satisfactory. He decomposed strong solutions of common salt, nitrate of silver, and superacetate of lead, and he inferred that the *under* surface of the organ corresponds to the zinc, and the upper surface to the copper extremity of the Voltaic battery. In the deviation of the needle in the multiplier produced by the torpedo, the action of its under surface corresponded with the zinc plate, and that of the upper surface with the action of the copper plate. In like manner, the extremity of a needle that received polarity from a torpedo when placed in a spiral wire, had *southern* polarity when it was nearest the *under* surface of the fish, and the other extremity of course northern. In one experiment Dr Davy connected the spiral with the multiplier, and having charged the former with eight needles, a single discharge from an active fish moved the needle in the multiplier powerfully, and converted all the needles into magnets, each of them as strong as if one only had been used.

Substance of its organs.

Dr Davy's next object was to ascertain "the exact nature of the substance of the electrical organs, or the peculiar structure of which they are composed." The electrical organs when wet weighed 302 grains; and when completely dried by sixteen hours exposure to the boiling heat of water, they weighed only twenty-two grains. They appeared to him to consist of 7·28 of matter not evaporable at 212°, and of 92·72 water. When the electrical organs are immersed in boiling water, they suddenly contract in all their dimensions, and the columns, from pentagonal, which they generally are, become circular. The electricity of a small Voltaic trough, the shock of which was just perceptible, distinctly affected the voluntary muscles of the live torpedo, but did not in the least affect the electrical organs. Their substances appeared to be neither sensitive nor contractile by the application of other stimulants; and hence he infers that these organs "are not muscular, but columns formed of tendinous and nervous fibres, distended by a thin gelatinous fluid." Dr Davy never could observe satisfactorily in the fresh fish the horizontal partitions which Dr Hunter had counted. After describing more fully and accurately than Dr Hunter the distribution of the three great trunks of the nervous system, Dr Davy describes the mucous system, which forms a conspicuous part of the anatomical structure of the fish. It consists of several clusters and chains of glands, distributed chiefly around the electrical organs, at different depths beneath the cutis, and of strong transparent vessels of various lengths and sizes opening externally in the skin for the purpose of pouring out the thick mucus secreted by the glands, and destined for lubricating the surface. This system, which was not noticed by Dr Hunter, was described, but imperfectly, by Lorenzini. Dr Davy thinks that this system may not only be aided by, but also aid the secretion of the mucus. In comparing the phenomena of the torpedo with those of other kinds of electricity, Dr Davy notices the following points of difference: "Compared with Voltaic electricity, its effect on the multiplier is feeble; its power of decomposing water and metallic solutions is inconsiderable; but its power of giving a shock is great, and so also is its power of magnetising iron. Compared with common electricity, it has a power of affecting the multiplier, which, under ordinary circumstances, common electricity does not exhibit; its chemical effects are more distinct; its power of magnetising iron and giving a shock appears very similar; its power of passing through air is infinitely less, as is also (if it possess it at all) its power of producing heat and light."

These differences have been explained in different ways by different authors. Mr Cavendish endeavoured to account for them on the principles of common electricity. Mr Nicholson did the same with much ingenuity. Volta at first supposed that the superposition of the different cells in the columns, formed of substances some of which excite electricity by contact, while others transmit it, corresponds to that of the metallic and moist conductors of which the pile is composed; but he afterwards showed to Sir H. Davy another form of the pile, which he thought fulfilled the conditions of the organs of the torpedo; a pile of which the fluid substance was a very imperfect conductor, such as honey, or a strong saccharine extract, which required a certain time to be charged, and which, though it did not decompose water, communicated nevertheless weak shocks when charged. MM. Humboldt and Gay Lussac were more inclined to compare the action of the torpedo to a chain of small Leyden phials, like Cavendish, than to the Voltaic pile. In order to explain why no spark is given by the torpedo, Mr Cavendish proved by experiment that the distance through which the spark flies is inversely, or rather in a greater proportion than the square root of the number of jars; and hence the torpedo may contain sufficient electricity to give a shock, without being able to make it pass through such a space of air as is requisite for the production of the spark. He accounted also for the absence of every appearance of attraction and repulsion, from the known fact that the shock of a battery so weakly electrified as to be incapable of passing through a chain, which is the case with the electricity of the torpedo, is not capable of producing any divergency in the pith balls of an electrometer. Mr Cavendish corroborated these views by constructing an artificial torpedo of thick leather, connected with glass tubes and wires, and covered with a piece of sheep-skin leather, which was an exact imitation of the real torpedo. The battery was composed of forty-nine jars of very thin glass, and contained about seventy-six feet of coated surface.

Humboldt has enumerated the following species of the torpedo which are electrical: Torpedo narke, *Risso;* torpedo unimaculata; torpedo marmorata; torpedo Galvanii.

Art. 3. *On the Electricity of the Gymnotus Electricus.*

Electric of the gy notus.

The electrical eel of Surinam, or *gymnotus electricus*, possesses electrical organs different from those of the torpedo, and exhibits different electrical properties. Its common size is about *three* feet in length; though Dr Bancroft was told that some have been seen in the Surinam river upwards of twenty feet long, and whose shock proved immediately fatal.

Richer was the first person who made known in Europe the electrical properties of this fish; and experiments have been since made upon it by various naturalists. It is from the observations, however, of Dr Williamson of Philadelphia, Dr Garden of Charlestown, and Mr Walsh, that our knowledge of its properties is derived; and these may be summed up in the following manner:

1. When the gymnotus is touched by the hand, a shock is felt in the fingers, and often as far up as the wrist and elbow; and when it is touched with an iron rod twelve inches long, the shock is felt in the finger and thumb.

2. If the eel is provoked by one person, the hand of another person held in the water will experience a small shock.

3. When the eel was touched and provoked with one hand, and the other held in the water at a small distance, a shock passed through both arms; and the same effect was produced when the hand held a wet stick in the water; and when the same experiment was made by eight or ten persons who joined hands, a shock was also experienced.

4. When the first of eight persons pinched the tail, while the last touched the head, they all experienced a severe shock.

5. The shock of the eel was found to pass through those substances which are conductors, and to be stopped by those which are non-conductors, of common electricity.

6. An insulated person electrified, exhibited no marks of electricity; and pith balls refused to diverge either when suspended over the eel's back, or touched by an insulated person when he received the shock.

7. Dr Williamson succeeded in making the electricity of the eel pass through a small space of air, and exhibit the electric spark when the fish was in the open air; but the spark is not visible when the fish is placed in water.

In the preceding experiments the gymnotus was in a enome- and aws.

large vessel, supported by pieces of dry timber about three feet above the floor. A small hole having been bored in the vessel, a person who held his finger in the stream of water which flowed from it experienced a shock when the eel was irritated.

Dr Williamson threw a cat fish into the same vessel with the gymnotus, and in a short time it gave the cat fish a shock, and caused it to turn up its belly and remain motionless.

erva- s of lberg.

Experiments on the gymnotus have more recently been made by M. Fahlberg of Stockholm, and by MM. Humboldt and Bonpland. The Swedish philosopher succeeded in obtaining an electric spark from the eel when placed in the air, by interrupting the conducting chain by two gold leaves pasted upon glass, and a line distant from each other; but he never could discover any phenomenon of attraction or repulsion, though he employed very delicate electrometers, and caused very strong shocks to pass through them.

Hum- lt and pland.

While MM. Humboldt and Bonpland were in South America, where the little streams, and even the basins of stagnant water, are filled with electrical eels, they enjoyed the finest opportunities of studying the phenomena of their electrical action. Having imprudently placed both his feet on a fresh gymnotus, Humboldt experienced a more dreadful shock than he ever received from a Leyden phial, and which left a violent pain in his knees, and in almost every joint, during the rest of the day. When both he and M. Bonpland held a fish, the one by the head or by the middle of the body, and the other by the tail, and, standing on the ground, did not join hands, one of them received shocks which the other did not feel; and hence they concluded that the eel could direct its strokes where it chose, or towards the point where it was most strongly irritated, sometimes discharging them from the whole surface of its body, and sometimes from one point only.

The gymnoti that had been rendered extremely tame during their voyage from Surinam to Stockholm were made to fast a long time, and when fishes were put into the tub they killed them at a distance, the electrical stroke passing through a very thick stratum of water. A fresh-caught gymnotus was placed by Humboldt beside little tortoises and frogs, which, ignorant of their danger, placed themselves upon its back. The frogs did not receive the shock till they touched the body of the eel. When they recovered they leapt out of the tub. Humboldt remarks that this gymnotus was not yet sufficiently tamed to attack and devour frogs.

Upon cutting a very vigorous fish through the middle of the body, Humboldt observed that the fore part alone gave shocks. The shocks, however, are equally strong in whatever part of the body the fish is touched, though it is most disposed to dart them forth when the pectoral fins, the electrical organ, the lips, the eyes, or the gills are pinched. Humboldt remarks that no person has ever perceived a spark issue from the body of the fish itself. He irritated it for a long time during the night, at Calabozo, in perfect darkness, without observing any luminous appearance.

thod of ing the mnoti h ses.

The method of fishing the electrical eels by horses, as described by Humboldt, is too interesting to be omitted in a popular article. The Indians having brought about thirty wild horses, forced them to enter a pool of muddy water surrounded with fir trees. "The extraordinary noise caused by the horses' hoofs makes the fish issue from the mud, and excites them to combat. These yellowish and livid eels, resembling large aquatic serpents, swim on the surface of the water, and crowd under the bellies of the horses and mules. A contest between animals of so different an organization furnishes a very striking spectacle. The Indians, provided with harpoons and long slender reeds, surround the pool closely; and some climb upon the trees, the branches of which extend horizontally over the surface of the water. By their wild cries, and the length of their reeds, they prevent the horses from running away, and reaching the banks of the pool. The eels, stunned by the noise, defend themselves by the repeated discharge of their electric batteries. During a long time they seem to prove victorious. Several horses sink beneath the violence of the invisible strokes which they receive from all sides in organs the most essential to life, and, stunned by the force and frequency of the shocks, disappear under the water. Others, panting, with mane erect, and haggard eyes expressing anguish, raise themselves, and endeavour to flee from the storm by which they are overtaken. They are driven back by the Indians into the middle of the water; but a small number succeed in eluding the active vigilance of the fishermen. These regain the shore, stumbling at every step, and stretch themselves on the sand exhausted with fatigue, and their limbs benumbed by the electric shocks of the gymnoti.

"In less than five minutes two horses were drowned. The eel being five feet long, and pressing itself against the belly of the horses, makes a discharge along the whole extent of its electric organ. It attacks at once the heart, the intestines, and the *plexus cœliacus* of the abdominal nerves. It is natural that the effect felt by the horses should be more powerful than that produced upon man by the touch of the same fish at only one of its extremities. The horses are probably not killed, but only stunned. They are drowned from the impossibility of rising amid the prolonged struggle between the other horses and the eels.

"We had little doubt that the fishing would terminate by killing successively all the animals engaged; but by degrees the impetuosity of this unequal combat diminished, and the wearied gymnoti dispersed. They require a long rest and abundant nourishment to repair what they have lost of galvanic force. The mules and horses appear less frightened; their manes are no longer bristled, and their eyes express less dread. The gymnoti approach timidly the edge of the marsh, where they are taken by means of small harpoons fastened to long cords. When the cords are very dry the Indians feel no shock in raising the fish into the air. In a few minutes we obtained five large eels, the greater part of which were but slightly wounded. Some were taken by the same means towards the evening."

The gymnotus is the largest of the electrical fishes. A fish of three feet ten inches long, obtained by Humboldt, weighed twelve pounds. The transverse diameter of the body was three inches five lines. The gymnoti of the *Cano de Bera* are of a fine olive-green colour. The under part of the head is yellow mingled with red. Two rows of small yellow spots are placed symmetrically along the back, from the head to the end of the tail. Every spot contains an excretory aperture, which keeps the skin of the animal covered with a mucous matter, which, as Volta has proved, conducts electricity twenty or thirty times better than pure water.[1]

Electrical organs of the gymnotus. Plate CCXIII. Fig. 2.

Dr Hunter examined, with his usual skill, the electrical organs of this fish; and in fig. 2 we have copied his engraving of it, in which the skin is removed to show the structure. In this figure A represents the lower surface

Phenomena and Laws.

---

[1] Humboldt notices it as remarkable that no electrical fish is covered with scales.

of the head; C, the cavity of the belly; B, the anus; E, the back, where the skin remains; GG, the fin along the lower edge of the fish; EE, the lateral muscles of this fin, removed and laid back with the skin to expose the small organs; L, part of the muscle left in its place; FF, the large electrical organ; HHH, the small electrical organs; *mmm*, the substance which separates the two organs; and *n*, the place where this substance is removed. These organs occupy nearly one half of the part of the flesh in which they are placed, and form more than one third of the whole fish. There are two pair of electrical organs of different sizes, and placed on different sides; the large one F occupies the whole of the lower and lateral part of the fish, constituting the thickness of its fore part, and extending from the abdomen to near one end of the tail, where it terminates nearly in a point. The two organs are separated at the upper part by the muscles of the back, at the lower part by the middle partition, and by the air bag at the middle part. The lesser organ stretches along the lower edge of the fish, and nearly as far as the other, terminating almost insensibly near the end of the tail. The two small organs are separated from each other by the middle muscle, and by the bones in which the fins are articulated. The large organ may be seen by merely removing the skin, which adheres to it by a loose cellular membrane; but in order to see the small organ, the long row of small muscles which move the fin must be removed. The electrical organs consist of two parts, viz. flat partitions or septa, and thin plates or membranes intersecting them transversely. The septa are thin parallel membranes stretching in the direction of the fish's length, and as broad as the semidiameter of the animal's body. The septa vary in length, some of them being as long as the whole body. In a fish two feet four inches long, the distance of the septa was nearly half an inch; and in the broadest part of the organ, which was one and a quarter inch, there were thirty-four septa. In the small organ the septa have a somewhat serpentine direction. They are only the fiftieth of an inch distant, and there are fourteen septa in the breadth of the organ, which is half an inch. The very thin plates which intersect the septa have their breadth equal to the distance between any two septa. There is a regular series of these plates from one end of any two septa to the other end, 240 of them occupying a single inch.

ART. 4. *On the Electricity of the Silurus Electricus.*

Silurus electricus. Fig. 3.

The silurus electricus, of which we have given a drawing in fig. 3, is a fish about twenty inches long, which is found in the Senegal, the Niger, and the Nile. It is eaten by the Egyptians, who dress its flesh, and salt its skin as an aphrodisiac medicine. The shock of this fish is distinctly felt when it is laid on one hand, and touched by an iron rod six feet long held in the other. Its electrical organs, according to M. Geoffroy, are much less complicated than those of other electrical fishes. They lie immediately below the skin, and stretch all round the body of the animal. Their substance is a reticulated mass, the meshes of which are clearly visible, and these cells are filled, like those of other electrical fishes, with an albuminous gelatinous matter. The nerves distributed over the electric organs proceed from the brain, and the two nerves of the eighth pair have a direction and nature peculiar to this species.

ART. 5. *On the Electricity of the Tetraodon Electricus.*

Tetraodon electricus.

In the cavities of the coral rocks in Johanna, one of the Canary islands, Lieutenant Paterson discovered the tetraodon electricus, which he found to possess the properties of other electrical fishes. It has a long projecting mouth, and is seven inches long and two and a half broad. The colour of its back is brown, of its belly sea-green, of its sides yellow, of its fins and tail sandy-green. Its body is covered with red, green, and bright white spots. It has large eyes, and its iris is red, tinged with yellow on its outer edges. It is found also in the American seas.

Lieutenant Paterson found this fish in water whose temperature was 56° or 60° Fahrenheit; and having caught two of them in a linen bag, he had no sooner taken one of them in his hand than he received so severe a shock that he was obliged to let it go. He carried the two fishes to the camp, and though one of them died, and the other was in a state of great debility, he was able to obtain the evidence of the surgeon and the adjutant in favour of his discovery. The former having held it between his hands, received a distinct electrical shock, and the latter received a shock by merely touching the fish on its back with his finger.

ART. 6. *On the Electricity of the Trichiurus Electricus.*

Trichiuru electricus

This fish, which we believe is the *Trichiurus Indicus* of Shaw, inhabits the Indian seas, and has been found to possess the power of giving an electrical shock. It has a pointed snout, and belongs to the family tænioides, of the order acanthopterygii.

Other ele trical fishe

Other electrical fishes have been met with, but the descriptions given of them do not enable us to determine whether or not they are the same as those which we have described in this section. Mr Maxwell, in his observations on Congo and Loango, mentions his having found at sea an electrical fish, which made the sailors who took it exclaim "that the devil was in the fish." When examining it attentively, Mr Maxwell found that his astonishment arose from his having received an electrical shock. Before each shock the skin upon its back and sides became very tense. It was like a cod, and weighed *thirty pounds*. He gave it to the natives to eat, and they praised it much. No electrical fish of such a size has, so far as we know, been found, and it is highly probable that it is a new species.

SECT. VI.—*On the Electricity of the Atmosphere.*

Electricit of the atmosphere

There is perhaps no branch of electricity so highly interesting as that which treats of the electricity of the atmosphere, whether we consider it in reference to ourselves as beings exposed to its tranquil as well as to its disturbed influence, or in reference to the grandeur and beauty of the phenomena which it exhibits.

The methods which have been adopted for examining the electricity of the atmosphere consist in elevating long vertical rods, the summits of which collect the electricity, or in extending insulated wires in a horizontal direction, or in sending up kites into the higher regions.

M. le Monnier, the Abbé Mazeas, Mr Kinnersley, Beccaria, Saussure, Ronayne, Cavallo, Read, Crosse, Ronalds, Schubler, &c. have made numerous experiments on the electricity of the atmosphere in its ordinary state. Le Monnier discovered that there was always more or less electricity in the atmosphere; that there was a regular diurnal period in which the electricity increased from sunrise, when it was scarcely perceptible, till three or four o'clock in the afternoon, when it reached its maximum; and that it again diminished till the fall of the dew, when it again increased, and subsequently diminished, till midnight, when it became insensible.

M. Beccaria found that the electricity of the air was always perceptible in a clear sky and calm weather. In rainy weather, without lightning, it always appeared a short time before the rain fell, and during its actual fall, but disappeared soon after the rain had ceased.

E eri- m s of Sa sure;

Saussure made many important observations on this subject. He found that the electricity of the air was very strong at nine o'clock in the morning; that it gradually diminished till six o'clock P. M., when the first minimum took place; that it afterwards increased to eight o'clock P. M., when the second maximum took place. It then diminished again with some irregularities till six A. M., when it reached its second minimum. It then increased again till eleven o'clock in the evening, when it again became a maximum. The electricity of the atmosphere has therefore a daily period, like the sea, increasing and decreasing twice in twenty-four hours. It, generally speaking, reaches its maximum intensity a few hours after sunrise and sunset, and descends again to its minimum before the rising and setting of that luminary. Saussure also observed that the electricity of the air is strongest during fogs, unless when they change into rain. Saussure likewise found that the electricity of clear weather is always positive; and the opinion of Volta is therefore highly probable, that the electricity of the atmosphere is essentially *positive*, and that the negative electricity which appears in rain, snow, and storms, is derived from more elevated clouds, which are electrified negatively by the discharge of a portion of their electricity into the earth or other clouds, in the same manner as an electrometer acquires negative electricity when it is touched at the instant that the air is electrified positively.

of rosse;

These results were confirmed by subsequent observers, whose observations we have not room more particularly to notice; but we shall make no apology for giving some account of the more recent and valuable observations of Mr Crosse and Mr Ronalds. Mr Crosse's experiments were made with an insulated copper wire, extending originally a mile and a quarter in length, and supported upon two masts from 100 to 110 feet high. The wire was one sixteenth of an inch thick. It was subsequently shortened to 1800 feet in consequence of its being exposed to depredations. From the observations made with this apparatus, which was in use eighteen months, Mr Crosse deduced the following conclusions.

1. The electricity of the atmosphere in its ordinary state is invariably *positive*. It is always fullest during the night. It increases at sunrise, diminishes towards noon, increases again towards sunset, and again diminishes to its nocturnal minimum.

2. The electrical state of the wire is disturbed by fogs, rain, hail, snow, and sleet. It becomes negative when they first come on. It frequently changes to positive, increasing gradually in strength, and then decreasing, a change from positive to negative occurring every three or four minutes.

3. The approach of a charged cloud at first sometimes produces positive and sometimes negative electricity. Its intensity increases and then diminishes and vanishes, being succeeded by the opposite electricity, which increases to a higher maximum, and then diminishes and disappears, and is again followed by the electricity which first appeared. In general the electricity increases at every repetition, till sparks issue in a copious stream from the conductor to the receiving ball, sometimes with interruptions, and again returning with fresh energy. When this happens, a powerful stream of air issues from the wire and the connecting apparatus. An explosive stream of electricity rushes from the one ball to the other at every flash of lightning, and a brilliant light is thrown upon surrounding objects. When the lightning increases, it is wise to let it pass into the ground.

4. The wire is almost as strongly electrified during a driving fog and a smart rain as during a thunder storm, and the electricity passes into opposite states in a similar manner.

5. A very feeble degree of positive electricity occurs in cloudy weather. When rain falls it changes to negative, and again becomes positive when the shower is over.

The following table contains a list of the different states of the air in which its electricity appears, those at the top of the list being those in which it is most powerful.

1. Regular thunder clouds.
2. Driving fog with small rain.
3. A fall of snow, or a brisk hail storm.
4. A smart shower in a hot day.
5. A smart shower in a cold day.
6. Hot weather after some wet days.
7. Wet weather after some dry days.
8. Clear frosty weather.
9. Clear warm summer weather.
10. A sky obscured by clouds.
11. Mackerel or mottled sky.
12. Sultry weather with light hazy clouds.
13. A cold damp night.
14. Weather during north-east winds, with a sensation of dryness and cold not shown by the thermometer.

Experiments of Ronalds,

By means of an electrical apparatus, founded on a new method of electrical insulation, Mr Ronalds made some interesting observations on Vesuvius at the time of moderate eruptions, and another series at Palermo during the prevalence of a sirocco. The rod of the electrometer was placed perpendicularly on the highest pinnacle of Mount Vesuvius, on the north side of the great crater, and about five hundred yards distant from it, a ravine being interposed. The following were the results:

on Vesuvius;

1. The electricity was *always* positive.

2. The intensity of it increased as the sun rose, unless when it was affected by the explosions of the volcano. Very frequent variations took place in the intensity, sometimes accompanying changes of the wind, sometimes following explosions from the crater, sometimes attending the approach of vapour from an aqueous fumerole, when the intensity of the electricity was always increased, and sometimes occurring without any apparent cause.

3. The black fumes from the old crater diminished the intensity more frequently than the white fumes, and very rarely increased it. Mr Ronalds supposes that the black fumes may be in a negative state; and that the white fumes, consisting principally of aqueous vapour, sulphuric and muriatic acids, and sulphur, may, when these vapours are condensed, and when the sulphur sublimes in the air, be brought into a positive state; and that these two states of the two fumes may sometimes act separately on the electrometer, or sometimes wholly and sometimes partially neutralize each other, either by induction or position, or by a discharge from the one to the other.

at Palermo.

The observations of Mr Ronalds on the electricity of the atmosphere during a dry sirocco, were made on the roof of Page's hotel, in Palermo. The electricity was always *positive*, the straw electrometer of Volta varying from five to twenty-one degrees. The electrical phenomena were diametrically opposite to those of the ordinary state of the atmosphere in serene weather, as the electric tension increases almost progressively from sunrise till the hottest part of the day, viz. about three o'clock P. M., when it gradually declined until sunset.

In the arctic regions in 1819–20, there were no sensible indications of electricity "in the summer months, when the clouds become more dense and frequent, and even when a slight shower of rain falls."

Observations of Schubler.

A series of most interesting observations have been recently made by Professor Schubler of Tubingen, on the electricity accompanying the condensation of aqueous vapours in the atmosphere, as affected by the direction of the winds. They were carried on during thirty months, between January 1805 and August 1811. The *first* series was made at Ellvanguen, during sixteen months, from January 1805 to April 1806; and the *second* at Stuttgard, during fourteen months, from June 1810 to August 1811. Ellvanguen is situated 1331 feet above the sea, in 48° 57′ 25″ of N. lat., and Stuttgard at 847 feet, in N. lat. 48° 46′ 32″. Professor Schubler observed no fewer than four hundred and twelve atmospherical precipitations. He used the straw electrometer of Volta, and a simple condenser; and in storms he never pushed his observations beyond the 600th degree of the instrument.

The following table contains the results of these observations.

Direction of the Winds corresponding to the Observations.	Number of observed Precipitations, classed according to the Nature of their Electricity.		Ratio of the Number of Positive and Negative Precipitations.	Mean Intensity of each of the two Electricities.		Mean Intensity of the Electricity, without considering its Nature.	Total Number of Precipitations observed.
	Positive.	Negative.		Positive.	Negative.		
North........................	12	11	100 : 91	131	99	116	23
North-east....................	11	12	100 : 109	105	132	120	23
East..........................	3	5	100 : 166	15	13	13	8
South-east....................	4	7	100 : 175	19	10	13	11
South.........................	5	13	100 : 260	26	23	24	18
South-west....................	28	65	100 : 232	66	33	44	93
West..........................	73	106	100 : 145	75	39	53	179
North-west....................	25	32	100 : 128	31	46	40	57
The three north winds, N.W.—N.—N.E....	48	55	100 : 114	74	75	75	103
The three south winds, S.E.—S.—S.W......	37	85	100 : 230	57	26	39	122
The three west winds, S.W.—W.—N.W....	126	203	100 : 161	57	38	48	329
The three east winds, N.E.—E.—S.E.......	18	24	100 : 133	71	72	72	42
All the winds..............	161	251	100 : 155	69	43	53	412

From these observations Professor Schubler draws the following conclusions:

1. The ratio of the *positive* to the *negative* precipitations follows a regular variation, setting out from the north or south wind, and proceeding either by the *east* or *west* winds.

2. By a *north* wind, the positive precipitations are a little more frequent than the negative ones; by a *south* wind, the *negative* precipitations are more than *double* the *positive* ones.

3. The negative precipitations, by the three south winds, viz. south-east, south, and south-west, are double those by the three *north* winds, viz. north-west, north, and north-east, the ratio being 114 to 230.

4. The *east* and *west* winds hold a mean in this respect. The *former*, however, approach more to those of the *north*, and the *latter* to those of the *south*, the electricity being oftener *negative* by the three *west* winds than by the three *east* winds in the ratio of 161 to 133.

5. The electricity of all the observed precipitations is oftener negative than positive in the ratio of 155 to 100.

6. The mean intensity of the *positive* electricity is, on the contrary, more considerable than that of the *negative*, in the ratio of 69 to 43.[1]

7. The intensity of the electricity, abstraction being made of its nature, is the *strongest* by the three north winds, particularly the north-east and north.

8. The electricity is at an average the weakest by the three south winds. Its intensity is by these three winds in the ratio of 39 to 75 weaker than by the three *north* winds.

9. By the three *east* winds the electricity is in the ratio of 72 to 48 stronger than by the three west winds.

10. The mean intensity of the electricity of all the precipitations, whether positive or negative, observed *in all directions of the winds*, is almost the same as that of the electricity of the precipitations observed *during the west winds alone*.

11. During the *north* and *east* winds the opposite electricities appear most distinctly, and almost with equal intensities. The *west* winds, and particularly the *south*, exhibit, on the contrary, a more feeble electricity, but a greater number of negative precipitations.

12. The *greatest* number of electrical precipitations takes place during *west* winds, and the *least* during *east* winds. The mean direction of the wind during the whole of the precipitations is 86°·9, making use of the formula of Lambert, in which the south is marked by 0°, the west by 90°, the north by 180°, and the east by 270°. The number 86°·9 corresponds with the WEST with four degrees of declination to the south-west.

With respect to the cause of the phenomena now described, Professor Schubler is of opinion, that at the moment of the precipitation of the vapours in our atmosphere, *positive* electricity is at first developed, and the *negative* appears to arise most frequently from the influence of the former. The precipitations which first take place during storms, or passing rains and snows, are commonly *positive*, and are soon followed with *negative* ones of nearly equal intensity. This alternation often happens several times, during which the drops of rain, hailstones, sleet, and snow, continually vary in their size, density, and continuity. At last the electricity growing weaker and weaker, ends by remaining negative; and sometimes after the storm a rain falls with negative electricity.

---

[1] Considering the quantity of the two electricities as made up of their intensity, and the number of times that either of them is observed, the ratio of the quantities of positive and negative electricity observed will be 690 to 666, nearly that of equality.

It is however not uncommon to see regular and continuous rains *negative* from their commencement, and during whole days. This fact, together with the feeble intensity of this kind of electricity, seems to favour the opinion that it is often owing to the partial evaporation experienced by the drops of rain during their fall.[1] In confirmation of this he adduces the fact of the negative electricity of the fine aqueous dust at the foot of cascades, which is sometimes so strong in large waterfalls as to make the electrometer diverge more than 100 degrees.

This explanation, Professor Schubler alleges, agrees also with the great frequency of *negative* rains in *south* winds, and of *positive* ones in *north* winds. A current of warmer air, and consequently more light and more elevated, in the first case ought to facilitate the evaporation of drops of rain during their fall; whilst, by the colder north wind, and consequently more heavy and nearer the surface of the earth, the clouds have in general a lower position, and the evaporation of the drops of rain is less easy, and almost nothing.

From these observations it also follows that we must not infer the negative state of the cloud from the negative electricity of the rain which falls from it; for it may happen that rain coming from clouds slightly positive, may become negative by the partial evaporation of the falling drops.

M. Schubler also remarks, that the great intensity of the electricity, and the distinct manner in which the two electrical principles alternately predominate during *north* and *east* winds, seem to arise chiefly from the dryness of the air during their continuance; to which we must add the situation of the clouds brought by these winds near the surface of the earth, the electricity of which may then naturally exert a more sensible influence upon our instruments.

The positive electricity of the atmosphere was found by Saussure to increase in intensity in proportion to the height at which it was collected. When MM. Gay Lussac and Biot ascended in a balloon, they collected atmospheric electricity from the clouds below them, by suspending a wire about 160 feet long from the balloon, and stretching it with a ball of metal. The electricity collected at the upper end of this thread was very perceptible in their electroscope; and when it was examined with a stick of sealing-wax, it was found to be *resinous* or *negative*, although the weather was perfectly serene. This result, though apparently inconsistent with the observations of Saussure and others, has been shown by M. Biot to be perfectly reconcilable with them. In fig. 4, Plate CCXIII. let WW′ be the wire, let us call A the stratum of atmosphere through which the wire passes, B the stratum above this, and C the stratum below it; and let us suppose, what is true, that the atmosphere has positive electricity, which increases with the height. The *positive* electricity in the superior stratum A will attract the *negative* electricity of the wire WW′ with a force equal to + P, and will repel the positive electricity of WW′ with a force equal to + N. The positive electricity in the lower stratum C will do the very same, but in an opposite direction, and with an inferior degree of force, viz. + p and + n, since the electricity increases with the altitude. Hence it follows that the negative electricity of the wire will be attracted towards its upper end by an excess of force equal to $P - p$, and the positive electricity will be repelled to its lower end with an excess of force $N - n$. To MM. Gay Lussac and Biot, therefore, who observed the electricity of the wire at its upper end, the electricity should be *negative;* and to M. Saussure and others, who observed it at its lower end, it should be *positive*.

te XIII. 4.

Upon the same principle, M. Biot explains a very interesting experiment made by M. Hermann. A very sensible electroscope with gold leaves is fixed at a certain height in the atmosphere when the weather is clear, and it there gives no perceptible indications of electricity. A metallic wire, or any other conductor, placed horizontally at the end of an insulating rod, is then placed and kept a short time in a stratum of air a few feet only above the electroscope. It is afterwards quickly brought down so as to touch the electroscope, and the gold leaves diverge with *vitreous* or *positive* electricity; but if, on the contrary, the insulated wire is placed and kept a short time in a stratum of air below the electroscope, and is then quickly raised and made to touch the electroscope, the leaves will diverge with negative electricity. In order to explain these opposite results, we must consider that the insulated conductor is charged at each time with the degree of electricity which belongs to the stratum in which it is placed. When it is carried rapidly, therefore, so that its state is not quite destroyed by the contact of the molecules of air among which it is placed, it will communicate this state to the electroscope. If it comes from *above*, it will carry to it an excess of *positive* electricity; if it comes from *below*, it will carry to it a defect of the same electricity, or an excess of *negative* electricity. "In general," says M. Biot, "let + E be the quantity of free vitreous electricity which the insulated conductor ought to possess, in order to be in a state of electrical equilibrium in the stratum of air where the electroscope is placed, so that whilst it has + E, the molecules of air of this stratum neither give nor take any thing from it. Let it now be carried to a superior stratum, where it takes $E + \delta E$, δE indicating the small excess of vitreous electricity which it has there taken. If we then bring it back quickly into the stratum of the electroscope, it will have $+ \delta E$ too much, and it will communicate this excess to all bodies that touch it. It will communicate it also to the electroscope if it touches it promptly, and, until the latter has lost by the contact of the air this excess which it has imparted, its leaves will diverge vitreously. On the contrary, when the insulated conductor returns from the lower region, it has $E - \delta E$ of vitreous electricity. If we make it touch the electroscope, the latter will partake of its state. Then the quantity of vitreous electricity which it will possess can no longer be in equilibrium with the influence of the mass of the surrounding air, and its natural fluid will be decomposed. But the excess of vitreous fluid which will result from this cannot cause the gold leaves to diverge, because its repulsive force will be wholly employed in compensating that of the exterior electricity E. The repulsive force, then, of the resinous will alone be exerted, because nothing compensates it;

---

[1] M. Delarive is of opinion, not only that the evaporation thus occasioned must be very feeble, considering that the air is charged and almost always saturated with humidity; but that if it did take place, it could not generate electricity, as M. Pouillet has shown that the conversion of pure water into vapour produces no electricity. He is disposed to seek for the cause of the negative electricity of rain either in the mechanical action of the air on the falling drops, or in the sudden change of temperature which they experience.

and the gold leaves will diverge in virtue of this electricity, until it has been carried away and neutralized by the immediate and successive contact of the molecules of air. Experiments of this kind present the unique case of an indefinite medium, which is air, of which all the molecules are individually charged with an excess of electricity of the same kind, adhering to their surface; so that the entire mass of the medium is found penetrated with it in a proportion which varies with the altitude. Consequently the different particles of this medium can only be at rest from the mutual compensation of their repulsive forces combined with their gravity; and the same condition is also applicable to conducting bodies which are immersed in it. Thus, for all these bodies the electrical equilibrium cannot take place when their natural electricities are completely neutralized, but only when they possess an excess of either electricity which corresponds to the stratum where they are found, an excess which is vitreous in the atmosphere when it is pure. If they possess a greater excess of this same electricity, they will act only in virtue of this excess upon each other, and upon all the molecules of the surrounding air. They ought, therefore, to repel one another mutually. If, on the contrary, the excess of electricity which they possess is less than that which they would naturally take in the stratum where we place them, the mass of the medium will act upon each of them in virtue of this difference, and their natural electricities will be decomposed as far as is necessary to supply what they want of the electricity of the medium. In virtue of this addition they will repel the medium as much as the medium repels them, and will experience no more action from it. But they will act upon each other with the excess of opposite electricity which they have acquired; and if the medium is an indefinite fluid composed of particles susceptible of electrifying itself by contact, this excess will gradually dissipate in space. Many curious experiments would be necessary to establish the laws of electrical equilibrium, under circumstances sufficiently different from those which we have been generally accustomed to consider."

Electricity of clouds.

The electricity of clouds was noticed by some of the earliest writers on the electricity of the atmosphere. Canton observed that certain clouds were charged with positive and others with negative electricity; and he noticed that the electricity indicated by his apparatus often changed five or six times in half an hour. This fact was confirmed, as we have seen, by the observations of Mr Crosse. These irregularities, however, remained unexplained till Mr Luke Howard distinctly proved that the electricity at the circumference of a nimbus is *negative*, while that of the centre is *positive;* and he suggested it as an interesting subject of inquiry to ascertain if the *negative* electricity was *descending* and the *positive ascending*. Mr J. Foggo undertook this inquiry, and in 1823 he erected a conductor armed with a smoking match, and erected from a south window. On the 12th of March 1824 there was a brisk wind from the north-west, with frequent showers all around. About three P. M. large dense clouds, which discharged heavy showers of hail, passed over the zenith. Between the showers the electricity was always positive, and the leaves of the electrometer showed their maximum divergency. So powerful indeed was the electrical state of the air, that by rubbing the outside of the glass of a detached electrometer with soft leather, the leaves opened more than forty degrees. During the showers, or when the clouds were over head, though no precipitation took place, the electricity was invariably positive, and so strong that sparks could at any time be drawn by the finger from the conducting wire. Mr Foggo likewise ascertained that by taking hold of the wire he could at pleasure intercept the electric fluid from reaching the instrument, so that the charge must have been received from the atmosphere or cloud. When the edge or the circumference of the cloud was nearly over the conductor, the electricity became negative, and appeared to be fully as strong as when it was positive. Mr Foggo, however, now found that it could not be intercepted as formerly by taking hold of the wire, or by touching it with a pointed steel rod. Hence he concluded that the electricity was not proceeding from the cloud as before, but was given off by the earth to the cloud. When the steel point was presented to the instrument, the divergence was so much increased as to endanger the gold leaf, and sparks were heard to pass rapidly between the point and the electrometer, while sharp pricks were experienced when the finger was brought near the brass cap.

Identity of electr- city and lightnin

Such are the general electrical phenomena of the atmosphere during its ordinary changes; but they appear with new splendour, and at once rouse the interest of the philosopher and the dread of the vulgar, when they are exhibited in the terrific grandeur of thunder and lightning. We have already seen that various writers had pointed out the identity of lightning and the electric spark; and though Franklin has obtained the special honour of having been the first who brought down fire from heaven,

> Arripuit fulmen cœlo, sceptrumque tyrannis,

yet he was no more the first who snatched the thunderbolt from heaven, than he was the first who wrested the sceptre from kings.

When Franklin called the attention of philosophers to the various points of resemblance between lightning and the electric spark, he conceived the idea of collecting the electricity of the atmosphere by means of pointed conductors, and of thus preserving buildings from its explosions. One of the first philosophers who endeavoured to verify these views was M. Dalibard, who, at the instigation of Buffon, erected an atmospherical conductor at Marly le Ville, about six leagues from Paris. An iron rod, forty feet long, an inch in diameter, and pointed at its upper end, was erected in a garden upon three large poles, and insulated by silken strings, and a stool with glass feet. In M. Dalibard's absence a thunder-storm appeared on the 10th May 1752, between two and three P. M., and M. Coiffier, who had the charge of the apparatus, drew sparks with a crackling noise from the lower end of it. Having called M. Raulet, the curate of the parish, this gentleman continued for some time, and in the presence of many of his parishioners, to draw large sparks of bluish fire from the conductor. A few days afterwards, on the 18th May, M. Delors drew similar sparks from a rod ninety-nine feet high, erected in Paris. The strongest of them were drawn at the distance of nine lines, and the conductor afforded sparks even when the cloud had moved at least two leagues from above the place of observation. On the 19th day Buffon obtained, at Montbar, similar evidence of the identity of electricity and lightning.

Observ- tions o Romas

In our history of electricity we have already given an account of the observations of the apparatus by which Franklin, in the month of June 1752, obtained sparks of electricity from the atmosphere during a thunder-storm. Attempts were everywhere made to repeat this remarkable observation; and the most successful of these was that of M. Romas, who, according to a decision of the Academy of Sciences, had invented the electrical kite more than a year before it was employed by Dr Franklin. The kite constructed by M. Romas was seven feet five inches high, three feet in its greatest width, and with a surface of eighteen square feet. The string was a cord wrapped round with copper wire. On the 7th June 1753 this kite was elevated to the height of 550 feet, by means of a string 700 feet long, and inclined 45° nearly. A silk cord three feet and a half long was fixed to its extremity, and suspended a large stone to govern the motion of the kite. A tube of white iron, about a foot long and an inch in diameter, was placed near the junction of the string and the silk cord, as a conductor, from which the sparks were to be drawn. From this conductor the spectators drew sparks with their fingers, keys, canes, and swords; and M. Romas having presented his knuckle, received a shock which struck him in the elbows, shoulders, breast, knees, and ankles. Seven or eight persons joined hands, and the shock struck the feet even of the fifth person. The storm now increased, and black clouds gathered in the zenith. At the distance of six inches sparks two inches long were obtained by a discharging rod. The electricity continuing to increase, flashes of fire about a foot long, three inches wide, and three lines in diameter, were frequently received, and the noise of them was audible at the distance of 500 feet. At this time he felt the sensation of a spider's web on his face when he was five feet from the string. The kite was now 650 feet high, and the wind blowing strong from the east, when M. Romas saw on the ground, about three feet from the white-iron tube, three straws dancing up and down below it. One straw was twelve, another five, and the third four inches long. The electricity having increased still more, the longest straw was attracted by the tube, accompanied with three loud sounds, which some compared to the crack of a postilion's whip, and others to that of a large pot of earthenware dashed in pieces on a pavement. This crash was heard even in the centre of the town, and the accompanying flash had the form of a spindle eight inches long and four or five lines in diameter. The long straw followed the string of the kite, and was seen moving with great rapidity even at the distance of ninety or a hundred yards, now attracted and now repelled by the string, each attraction being attended with long plates of fire and constant explosions. A phosphoric smell was distinctly felt. A permanent cylinder of light, about three or four inches in diameter, surrounded the string.

M. Romas again raised his kite on the 16th August, and though the storm was not severe, yet in an hour he obtained thirty beams of fire, nine or ten feet long, and about an inch thick, each accompanied by a noise like that of a pistol. When the glass of his discharging-rod was two feet long, he was able to conduct beams of fire six or seven feet long as easily as he had done those of seven or eight inches, without feeling the slightest shock. On this occasion the string of the kite was above a thousand feet long, and the metallic wire which was coiled round it was continuous throughout.

use of rolling thunder.

It is obvious, from the preceding facts, that the well-known phenomenon of thunder and lightning is entirely an electrical one, the lightning being the electric spark, and the thunder the sound which accompanies it prolonged by successive echoes from among the clouds. That the clouds are capable of reflecting sound was determined by direct observation on the sound of cannon, made by Messrs Arago, Matthieu, and Prony. They observed that in a perfectly serene sky the explosions of their guns were always single and sharp, whereas when the sky was overcast, or when a cloud came in sight and covered any considerable portion of the horizon, the sound of the gun was attended by a long-continued roll like thunder; and sometimes a double sound was heard from a single shot. Sir John Herschel, however, has pointed out another cause for the rolling of thunder, as well as for its sudden and capricious bursts and variations of intensity. "To understand this cause," says he, "we must premise that, *cæteris paribus*, the estimated intensity of a sound will be proportional to the quantity of it (if we may so express ourselves) which reaches the ear in a given time. Two blows, equally loud, at precisely the same distance from the ear, will sound as one of double the intensity; an hundred struck in an instant of time will sound as one blow a hundred times more intense than if they followed in such slow succession that the ear could appreciate them singly."

Now let us conceive two equal flashes of lightning, each four miles long, both beginning at points equi-distant from the auditor, but the one running out in a straight line directly away from him, the other describing an arc of a circle having him in its centre. Since the velocity of electricity is incomparably greater than that of sound, the thunder may be regarded as *originating* at one and the same instant in every point of the course of either flash. But it will reach the ear under very different circumstances in the two cases. In that of the circular flash, the sound from every point will arrive at the same instant, and affect the ear as a single explosion of stunning loudness. In that of the rectilinear flash, on the other hand, the sound from the nearest point will arrive sooner than from those at a greater distance; and those from different points will arrive in succession, occupying altogether a time equal to that required by sound to run over four miles, or about twenty seconds. Thus the same *amount* of sound is in the latter case distributed uniformly over twenty seconds of time, which in the former arrives at a single burst; of course it will have the effect of a long roar, diminishing in intensity as it comes from a greater and greater distance. If the flash be inclined in direction, the sound will reach the ear *more compactly* (i. e. in shorter time from its commencement), and proportionally more intense. If (as is almost always the case) the flash be zigzag, and composed of broken rectilinear and curvilinear portions, some concave, some convex to the ear; and if, especially, the principal trunk separates into many branches, each breaking its own way through the air, and each becoming a separate source of thunder, all the varieties of that awful sound are easily accounted for.

Distance of thunder.

The distance of the point in the atmosphere where the lightning is generated, may be readily computed by multiplying 109° by the number of seconds which elapse between the flash and the first stroke of thunder. The product will give in feet the distance required.

The general phenomenon of thunder and lightning occurs during the passage of electricity between two clouds oppositely electrified, or one of which has an inferior charge of the same kind of electricity; but it appears in its most appalling form when the accumulated electricity of the clouds descends to the earth, shivering the strongest oak in its passage, rending the thickest walls, setting fire to houses, or stacks, or forests, and instantly destroying animal life, when the frail tenement of man or of beast happens to obstruct its path, or afford to it a more easy transit. Sometimes, however, the thunderbolt passes from the earth to the clouds, and in this case it is called the *ascending thunderbolt*. The Marquis Maffei was the first who observed this curious phenomenon. He distinctly saw during a storm the lightning issue from the ground with a loud noise. The Abbe Lioni and M. Seguier of Nismes saw the lightning rise in the form of a flame six feet high, followed by a loud noise.

Ascending thunderbolt.

One of the most interesting cases of the ascending bolt has been recorded by John Williams, Esq. It took place upon the hills above the village of Great Malvern, on the 1st of July 1826. A party had taken refuge from the storm in a circular building roofed with sheet iron, and one of the ladies on entering the hut expressed her alarm lest the lightning should be attracted by the iron roof. They had scarcely entered their retreat, and were about to partake of some refreshment, when a violent storm of thunder and lightning came on from the west. About forty-five minutes past two, a gentleman who stood at the eastern entrance saw a ball of fire which seemed to him moving on the surface of the ground. It instantly entered the hut, forcing him several paces forwards from the doorway. On his recovering from the shock, he found his sisters on the floor of the hut, fainting, as he imagined, from terror. Two of the ladies had died instantly; another lady, and the rest of the party, were much injured. The explosion which followed the flash of lightning was said by the inhabitants of the village to have been terrific. Mr Williams, who immediately examined the hut, found a large crack in the west side of the building, which passed upwards from near the ground to the frame of a small window, above which the iron roof was a little indented. Mr Williams conceived it to be quite clear, from the place of the fragments of stone and other appearances, that the clouds were negatively electrified during this storm.

Electrical phenomena on mountains; on Mount Breven;

Various electrical phenomena of a very interesting kind have been observed by travellers when ascending lofty mountains. In 1767, MM. Saussure, Pictet, and Jallabert, when on the top of Mount Breven, received small electric shocks at their finger ends by stretching out their arms, and a whistling noise even accompanied them. The gold button on M. Saussure's hat yielded distinct sparks.

on Mount Ætna;

In 1814, a party of Englishmen experienced similar effects on Mount Ætna during a storm of thunder and lightning accompanied by a heavy fall of snow. One of the party felt his hair moving, and upon raising his hand to his head a buzzing sound issued from his fingers. The rest of the party experienced the same sensations, and by moving their hands and fingers they produced a variety of musical sounds, audible at the distance of forty feet.

on Ben-Nevis.

On the 27th of June 1825, Dr Hooker and a party of botanists witnessed effects like those described, during a fall of snow on Ben-Nevis when there was no thunder-storm. The snow fell very heavily for nearly two hours. Soon after it began, a hissing sound was heard everywhere around them, and continued about an hour and a half. It seemed to proceed from every point in the vicinity; and on arriving at the cairn on the summit of the mountain, they could almost determine the stones from which the electricity issued. The hair of several of the party exhibited, when touched, the usual electrical phenomena.

On the transport of ponderable substances by lightning.

Before quitting the subject of lightning, we must submit to our readers a brief account of the remarkable observations made by M. Fusinieri on the ponderable substances transported by lightning in its passage, and which it deposits in a permanent state on the bodies which obstruct its passage. When we consider the magnitude of the scale on which the great electrical machine of our atmosphere enables us to study its effects, it appears strange that so little attention has been paid to those interesting phenomena which accompany the electric stroke. M. Fusinieri is the only person who has made this an object of special investigation; and the results to which he has been led possess, as might have been expected, a very peculiar interest. The following are the general results which he obtained: Lightning contains, like the common electric spark, matter in a state of extreme division, and in a state of ignition and combustion. In the matter deposited by lightning on houses and on trees which have been struck by it, he has found *iron*, *sulphur*, and *carbon*. Lightning divides and subdivides itself indefinitely into sparks, which end in being not much larger than those of ordinary machines; and each of these sparks contains ponderable substances in the state of extreme division already mentioned. The lightning deposits the substances with which it is charged while it passes through them, and while it breaks hard bodies; and it deposits them on the surface by which it enters the body, as well as on that by which it escapes, and also on the surfaces of fracture. When the resistance to its passage is not great, it leaves no perceptible deposit; and the quantity of matter deposited increases, and is proportional to the difficulty with which the lightning traverses the body. At the same time that lightning deposits the matter which it contains, it takes up new matter from the combustible bodies, such as iron, charcoal, &c. through which it passes. The deposited matter tends always to expand itself in thin films on the surface which receives it, and it does this most readily on surfaces that are smooth and free from all asperities.

In examining the traces left by lightning when it fell at Vicenza in 1829, and at Padua in 1831, M. Fusinieri made the following observations: It deposited on the surface of a wall by which it entered the house, a thin layer of pulverulent matter, of a brown colour at its centre, and yellowish and much less deep at its margin. When this matter was collected and carefully examined, it proved to be *iron* in different degrees of oxidation. Upon some stones which the lightning had detached from the wall there was found a stratum the fiftieth of an inch thick, and of a brownish colour, which seemed to have undergone a species of fusion. This stratum was *sulphuret of iron*, which gradually changed into a sulphate of the same metal. M. Fusinieri indeed had previously found small crystals of sulphuret of iron upon an iron rod which the lightning had struck, and also upon a stone to which it had passed from the iron. The position of these crystals indicated that they had been formed in the middle of the passage of the lightning; a fact which he considered as proving that the electric matter could transport sulphur across metal itself. When the lightning escaped from the wall, it deposited upon the wood a dust composed of small aggregated grains, which had all the qualities of ferruginous matter. In pursuing the passage of the lightning, it was found to have divided itself into a great number of sparks more or less voluminous upon the windows, formed of pieces of rectangular glass united in a leaden frame. The traces left on the glass and on the lead were very slight, and there were only a few marks on the glass very near its contact with the lead. The traces on the lead were small cavities, round which there had been a fusion of the metal. Some of these cavities passed through the whole thickness of the lead, and their diameters varied with the size of the sparks that had produced them. In general, each cavity of any size was surrounded with several smaller cavities, which seemed to prove that each discharge was accompanied by smaller electric sparks disseminated around it. Besides these cavities, the lightning had spread on the surface of the metal a stratum of pulverulent matter, which adhered so strongly to the lead that none of it could be detached without removing at the same time a portion of the metal. Each large cavity was the centre of one of these strata, which appeared to be composed of globules of lead in the central part, and ferruginous dust on the margin. The glass, though an insulating body, was, as we have mentioned, marked also by the lightning. The origin of the thin strata formed on its surface was at those points where it had been in contact with the lead; but they extended much beyond this, and were composed at first of a powdery matter, sometimes blackish and sometimes whitish; and beyond this they terminated in continuous and diaphanous laminæ, which reflected the colours of thin plates. The central and pulve-

Phenomena and Laws.

rulent portion was lead; the exterior portion, and the thinnest, appeared to be iron more or less oxidated. On one occasion one of these thin plates was formed of an extremely thin stratum of metallic iron not oxidated. M. Fusinieri had formerly succeeded in diffusing metals in thin plates upon mercury by the common electric spark; and he considers the fact, that the same phenomenon takes place on glass as on mercury, as demonstrating that the effect is not owing to a molecular attraction of the surfaces, but solely by the property of expansion which is possessed in a state of fusion by those substances which are transported by the lightning. This property belongs in an especial manner to combustible bodies, particularly to metals, though these last do not all enjoy it in the same degree. Iron, for example, is more expansible than lead, as is demonstrated by the thin films which are deposited by electrical discharges.

M. Fusinieri next proceeds to describe the traces of iron, &c. which lightning deposits upon trees. By means of chemical re-agents and the magnetic needle he had previously determined that traces of iron had been left by lightning on two poplars and a pear-tree which it had struck; and he also found traces of sulphur at the extremity of the roots of a poplar tree, at which the lightning had escaped. These observations were confirmed subsequently by many others. A poplar having been struck at Casale, near Vicenza, on the 14th May 1829, M. Fusinieri found that the part of the trunk deprived of its bark was covered with small black spots, which he regarded as produced by the sparks already mentioned which had been disseminated by the electric current at the instant its bark was carried away. The bark itself must have been reduced into extremely small parts, and immediately consumed, for not a vestige of it could be found. It would appear also that the lightning had carried away a part of the wood which it decomposed, such as the carbon, while the rest was volatilized. Traces of sulphur were found at the foot of the tree; and the lightning having insinuated itself between the bark and alburnum of the roots, there was felt, by removing the former, a strong odour of sulphuretted hydrogen, similar to, though more powerful than, that which the traces of sulphur had left upon the ground. The roots torn asunder by the lightning were impregnated with a moist and brownish matter, which was extraneous, but which had penetrated into their organic tissue with the lightning which conveyed it. This matter exhaled the same fetid odour as the surrounding earth, especially that portion of the earth which, from being in contact with the roots, was impregnated with the same brownish matter. In penetrating farther into the earth, it was found traversed by serpentine furrows, covered with a cinereous matter, the odour of which was the same as that which was exhaled by the other traces of lightning. The serpentine form of these furrows clearly indicated the tendency of the lightning to disseminate itself. All these substances and deposits were carefully collected and examined by M. Fusinieri.

In a pear-tree which had been struck with lightning in 1827, M. Fusinieri discovered very remarkable effects. Though its trunk, three feet in diameter, was torn into four parts throughout its whole length, no foreign matter nor odour could be perceived either in its roots or in the earth. At the places where the branches joined the trunk, *the substance of the pear-tree* was altered to the depth of several lines. It had acquired an acid taste and a reddish colour. It exhaled while burning a penetrating and peculiar odour, and it continued to burn without flame till it was completely consumed. The matter of the lightning had therefore penetrated the tissue of the wood, and there presented traces of iron.

M. Fusinieri has collected and detailed many interesting observations respecting the substances deposited by lightning upon the various parts of houses which have been struck by it; but we regret that our limits will not permit us to pursue any farther this most important subject.

These and many other facts seem to prove that iron exists in the air and in clouds; and it is well known that the same metal mixed with manganese, nitrous salts, and organic substances, is found in rain water. M. Fusinieri is of opinion that the iron has been drawn from the earth, and chiefly from mountains, where the mines are most frequented, and where storms commonly begin to form.[1] The colouring matter of snow and rain, and the existence of meteoric stones, prove the existence in our atmosphere of dry and ferruginous vapours, the molecules of which are more or less rarefied or condensed according to the causes which may generate them. The fact that meteoric stones fall during the prevalence of storms and other electric phenomena, and especially the fact that hailstones have sometimes a nucleus of small pieces of sulphuret of iron, appear to M. Fusinieri to afford the true origin of these remarkable bodies. It has been already proved also, that electricity does transport matter; and when we consider, as Ampere has shown, that magnetic currents surround our globe, that matter in an extreme state of subdivision spontaneously expands itself, that radiating heat, like electricity, transports ponderable substances, we may obtain a very simple explanation of the origin of meteoric stones. As the temperature of the surface of the globe is not high enough to detach from it the material bodies which exist in the atmosphere, M. Fusinieri concludes that we ought to attribute this action to other causes, which are yet to be discovered, rather than deny a fact so completely demonstrated.

Fulminary tubes.

Among the remarkable effects of atmospherical electricity may be numbered the production of what are called *fulminary tubes*. These tubes are of different lengths, and are produced by the passage of lightning through beds of sand, the particles of sand being agglutinated by the action of the electric fluid. Dr Fidler has collected and described many of these tubes from different localities; and their electrical origin has been placed beyond a doubt. M. Hachette conceived the idea of imitating these tubes by using a strong electrical battery; and he and M. Savart and M. Beudant having placed a quantity of pounded glass in a hole made in a brick, and having caused the electrical discharge of the battery to pass through the pounded glass, they succeeded in forming tubes exactly similar to those formed by atmospherical electricity. One of those which they made was an inch long, its external diameter varying from one sixteenth to one eighth of an inch, and its internal diameter being the fiftieth of an inch. In another experiment, where a little chloride of sodium was mixed with the pounded glass, the length of the tube was an inch and a fifth, and of uniform diameter. Its mean external diameter was one fifth of an inch, and its internal diameter one twentieth of an inch. When they used powder of felspar or pounded quartz, they could not succeed in making the tubes.

Hail.

Among the phenomena of atmospherical electricity, one of the most interesting is the production of hailstones, particularly those of an enormous size. The connection

---

[1] The returning stroke of lightning, when it passes from mountains or places containing iron and other metals, must necessarily carry along with it these substances in a state of extreme subdivision. See p. 620.

Volta's theory.

Matteucci's theory.

between the formation of hail and an atmosphere highly charged with electricity has been long ago recognised; but our almost total ignorance of the subject may be inferred from the character of the hypotheses which have been framed to account for the production of hail. Volta supposes that a small globule of snow becomes a hailstone, gradually increasing in size by being kept in a state of reciprocating motion between two clouds charged with opposite kinds of electricity, until the gravity of the constantly increasing mass overpowers the electrical force, or till the electricity of the clouds is spent by their mutual re-action. M. Matteucci has justly objected to this strange hypothesis, that it is difficult to conceive how a hailstone nearly two pounds in weight could be formed by such a process. He denies that the clouds possess an electric force sufficient to produce such an effect; and, admitting that such a force does exist, he maintains that the electricity would be directly discharged from the one to the other. M. Matteucci conceives that the hailstones are produced instantaneously, and that they fall completely formed. He considers that there can be only two epochs in their formation, viz. the production of the snowy nucleus; and, secondly, that of the icy crust which covers it. When a cloud has its temperature greatly reduced, it is easy to conceive its surface covered with small flocks of snow; and if an electrical discharge should in this case pass through it, it would give rise to hail, by obliging the cooled vesicles to condense round each snowy nucleus. It is this shock, he observes, which is necessary to destroy the inertia of the particles, which ought to unite to each other, as is seen in the experiment of the congelation of water with the cryophorus of Wollaston. M. Matteucci was led to these views by studying the hail-storm which took place at Tussi on the 24th July 1832. About six o'clock A. M., after a brilliant sun, the whitish and scattered clouds were seen suddenly to unite, and to form a thick mass scarcely detached from the horizon, and which covered the country with a thick darkness, that continued uninterrupted by the effects of strong electrical discharges. An impetuous north-west wind soon rose, and was followed by copious rain mixed with hail. This storm, which lasted about fifteen minutes, was followed by a lucid interval, after which there fell a thick snow, which ceased and began again several times. "I do not wish," says M. Matteucci, "to cite any facts which might appear fabulous; but it appears certain that a hailstone was found which weighed *fourteen pounds*, and that another in falling upon a house forced its way through the roof; that trees from three to six centimeters in diameter were destroyed; that oxen were wounded, and that several walls were overthrown or rent by the force of the hail. I state as certain, the fact that hailstones collected a few instants after their fall, still weighed a pound and a half. M. Pouillet assures us that he can himself certify that hailstones have fallen half a pound in weight. I can certify that they have fallen three times that weight."

Paragreles.

In consequence of the demonstrated connection between hailstones and a certain electrical state of our atmosphere, M. Lapostolle, professor of physic at Amiens, proposed to protect vineyards and other cultivated grounds from the destructive effects of hail, by erecting wooden poles twenty-five feet high, for the purpose of carrying off the atmospherical electricity. The use of these hail-rods has extended itself over France, Switzerland, Germany, and Italy; and it is not easy to resist the evidence that has been collected of their efficacy, notwithstanding the opposition that they have met with from many scientific individuals. Each pole is supposed to protect a circle of a hundred or a hundred and thirty feet, in the centre of which they are placed. Rods of metal being too expensive, they are made of wood, in a way which will be described in a subsequent part of this article. Each rod does not cost more than a few shillings, and the practice is to take them up after having put them under cover with the other rural implements, and replace them at the vernal equinox.

Water-spouts.

Another phenomenon, which is either formed by atmospherical electricity or connected with it, is the water-spout, a meteor of rare occurrence, and often most destructive in its effects. That distinct electrical phenomena are developed during the continuance of certain water-spouts cannot be doubted; but the electricity has in these cases been supposed to be a secondary phenomenon, produced by the motion of the air. This view of the subject has received some support from the researches of M. le Comte Xavier de Maistre, who has succeeded in imitating the principal phenomena of water-spouts, and even the co-existing ascending and descending currents, by the mechanical circular motion of a liquid; and it is to this mechanism of the water-spout that the electrical phenomena are ascribed. The lower parts of the atmosphere, and those above the clouds, are brought to the same point by the two interior and opposite currents of the spout, and strata of air charged with vapour, and often with different electricities, are thus brought into union, and produce the electrical phenomena in question.

Sheet o summer lightnin

Matteu ci's the of sheet lightnin

The well-known phenomenon called *sheet or summer lightning* has recently been examined by M. Matteucci of Bologna. This ingenious author considers it to be proved that there is an accumulation of one of the two electricities at the surface of the earth; and he ascribes this electricity either to evaporation or to the analogous causes which M. Pouillet has substituted for it, or to chemical actions which are constantly going on in the interior of the earth. In order that this electricity may not escape and pass immediately into the mass of the globe, as soon as it is developed it is necessary that the ground in which it is accumulated may not be a conductor, either from its own nature, or in consequence of the evaporation which dries it. It is also chiefly in high and insulated places rather than in the plains, above rocks rather than above forests, in summer rather than in winter, in the middle of the day rather than in the night, that these stormy clouds show themselves, whose formation cannot be well accounted for but by the influence of the electricity which the ground retains. To what other cause, he asks, can we attribute those clouds which are sometimes suddenly formed on the flanks of mountains, and afterwards rise into the air, without any variation of temperature, any change of barometrical pressure, or any other apparent modification in the state of the atmosphere? In applying these principles to the explanation of summer lightning, he considers the electricity of the earth's surface to be detained there by the desiccation of the ground, which renders it an insulator. At the moment of sunset, and during the night, the vapours which are thus condensed by cooling near the ground form a conducting stratum which serves to re-establish by degrees the electrical equilibrium between the atmosphere and the earth, which are charged with opposite electricities. It is chiefly in the plains, he conceives, that we ought to observe sheet lightning; and it ought to last a much longer time, because on elevated and insulated places the flow of electricity accumulated during the day will be much more rapid, on account of their form and position in the middle of an atmosphere more rare, more cold, and consequently more highly charged with vapours. These electrical discharges between the ground and the atmosphere may, according to our author, take place with much force, and produce even violent effects, especially if the ground and the atmosphere are too much dried;

and he supposes that some earthquakes, and particularly those which take place after great droughts, may be owing to this cause. This supposition explains, in a satisfactory manner, the process employed by the ancients, and often with success, to protect from earthquakes those places which are subject to them, and which are particularly those where the nature of the ground renders the accumulation of electricity easy, and its escape difficult. This process consisted in sinking into the ground, even to a considerable depth, long bars of iron, which, according to the explanation given above, ought to facilitate the establishment of the electric equilibrium, by establishing a metallic communication between the interior of the ground and the surface, which, by its insulating faculty, retains its electricity.

urora bo-
lis.

Among the atmospheric meteors generated by electricity the aurora borealis holds a distinguished place. The phenomena which it exhibits have already been fully described under another article (the AURORA BOREALIS), but it belongs to our present subject to treat briefly of its electrical origin. The crackling and hissing noise of electricity passing from one place to another has been distinctly heard in this country by Mr Nairne and M. Cavallo, and we can ourselves bear testimony to the same fact. In the north of Europe the sound accompanying the northern lights is an universally admitted fact, and proves beyond a doubt that, in certain auroras at least, the atmosphere is highly charged with electricity. Mr Trevelyan learned when he was in Faroe that the peculiar smell which accompanies electrical discharges was distinctly felt during a brilliant aurora; and in the year 1821 Sir David Brewster had the good fortune to observe, at Belleville in Inverness-shire, an aurora the phenomena of which were actually combined with those of a thunder-storm. This case is so remarkable, and so instructive, that we shall give the description of it in his own words: "On the evening of the 29th August, about half past nine o'clock, P. M., when there was not a breath of wind, and when the thermometer stood at 63°, the noise of very distant thunder was heard towards the south; sheets of very brilliant lightning illuminated the sky, issuing in general from a small black cloud near the horizon. I was surprised, however, to observe, that, with the exception of a few thin black clouds, which were rendered visible by the lightning, the greater part of the sky was covered with shining masses, like those which form the aurora borealis. The stars were easily seen through this luminous matter, which was arranged in irregular masses separated by clear intervals, but having a tendency to assume the appearance of irradiations diverging from the cloud whence the lightning appeared to issue. When the lightning flashed, it was propagated in a particular manner along these masses of light; but, what was very singular, the luminous patches were constantly in a tremulous or undulating motion during the intervals of the flashes of lightning. They shifted their place and changed their form exactly like the light which appears in many of the varieties of the aurora borealis. As the luminous clouds now described did not appear in the northern part of the horizon, and were distinctly related in their position and form to the thunder-cloud from which the lightning emanated, we are entitled to refer the two classes of phenomena to the peculiar electrical condition of the atmosphere, and to suppose that the phenomena of the aurora borealis may have an analogous origin." It seems now to be clearly proved that auroræ exist not only at great heights in our atmosphere, such as from 62 and 105 miles, the lowest as given by Cavendish and Dalton, to 500 and even 1000 miles, as measured by other observers; but that they appear even close to the earth, in the lowest region of the atmosphere, is clearly established by a decisive observation of Captain Parry's.[1] In the first of these cases it would be in vain to look for electrical indications, when the meteor is so far beyond the sphere of our electroscopes and the reach of hearing; but, in the latter case, we may reasonably expect not only to observe the peculiar electric state of the atmosphere, but also to hear the sound which invariably accompanies the passage of the fluid. This view of the subject reconciles the apparently contradictory observations which have been made on the aurora; and the connection of the phenomenon with the magnetic meridian, as well as its influence in certain cases on the magnetic needle, present no difficulty since the recent discoveries respecting the connection between electricity and magnetism.

Fire-balls.

That the other luminous phenomena of the atmosphere have their origin in its electricity cannot be doubted. Fire-balls or globes of fire have been observed at altitudes from 30 to 100 miles, and moving with velocities varying from 5 to 33 miles in a second. These balls of light sometimes leave behind them a luminous track after they have vanished. Sometimes they explode into globes of a smaller size, sometimes they are dispersed into divided sparks, and at other times they are accompanied with showers of meteoric stones. Falling or shooting stars are only the same phenomena on a smaller scale; they appear at all seasons, but most frequently during the prevalence of the northern lights, and generally in the lower regions of the atmosphere. The prismatic columns of light which were observed by Mr Fisher and others in the arctic regions have obviously an electrical origin. "On the afternoon of the 25th October Mr Fisher observed at Winter Harbour two vertical columns of prismatic colours, about 15° on each side of the sun, which was below the horizon; they were about 5° long, and their lower end touched the horizon: they continued for about an hour, from noon to one o'clock. Similar columns were observed two or three times, and about the same time the aurora appeared.

Columns of light.

Fire of St Elmo.

The fire of St Elmo, or Castor and Pollux, is a brilliant light which frequently appears on the summits of ships' masts, on the points of bayonets, on the tops of spears, and on the tips of the ears of horses. It is obviously nothing more than the electricity discharging itself either from or into pointed bodies. Its connection with the electrical state of the atmosphere is obvious from the following account of the phenomenon as given by Lord Napier, who saw it in the Mediterranean in June 1818. "About nine, when the ship was becalmed, the darkness became intense, and was rendered still more sensible by the yellow fire that gleamed upon the horizon to the south, and associated by the deep-toned thunder which rolled at intervals in the mountains, accompanied by repeated flashes of that forked lightning whose eccentric course and dire effects set all description at defiance. By half past nine the hands were got aloft to furl the top-gallant sails and reef the top-sails, in preparation for the threatening storm. When retiring to rest, a sudden cry of St Elme and St Ann was heard from those aloft and fore and aft the deck. On observing the appearance of the masts, the main top-gallant-mast head, from the truck, for three feet downwards, was completely enveloped in a blaze of pale phosphoric light flitting and creeping round the surface of the mast. The fore and mizen top-

---

[1] Mr W. C. Trevelyan observed that the aurora borealis in Faroe and Shetland was often seen very low, not more than 40 or 60 feet above the sea, and he learned that in both countries it is distinctly heard.

Phenomena and Laws.

gallant-mast heads exhibited a similar appearance. This lambent flame preserved its intensity for the space of eight or ten minutes, and then it gradually became fainter, till it diminished at the end of half an hour."

An interesting case of the fire of St Elmo, in which the electricity first settled on the most prominent metallic body, and then on the bodies next in conducting power, is described in the memoirs of the Count de Forbin. "In the night," says he, "it became extremely dark, and it thundered and lightned fearfully. As we were threatened with the ship being torn to pieces, I ordered the sails to be taken in. We saw upon different parts of the ship above thirty St Helmo's fires; amongst the rest was one upon the top of the vane of the mainmast, *more than a foot and a half in height.* I ordered one of the sailors to take the vane down; but scarcely had he taken the vane from its place, when the fire fixed itself upon the top of the mainmast, from which it was impossible to remove it."

Sometimes the electricity of the atmosphere shows itself at the yard arms and mast heads of vessels, in the form of balls of fire. Captain Clavering of the Griper experienced a severe gale, which lasted three days without intermission, when about 100 miles to the west of the Fiord of Drontheim. This gale was remarkable for the small amount of the effect produced on the barometer, on its approach, during its continuance, or after its cessation; and Captain Clavering was induced, from this and other causes, to ascribe it to a disturbed state of electricity in the atmosphere. It was accompanied with very vivid lightning, which is particularly unusual in high latitudes during winter, and by the frequent appearance and continuance for several minutes of balls of fire at the yard arms and mast heads. Of these no fewer than *eight* were counted at one time. This phenomenon is obviously an interesting variety of the fire of St Elmo.

The observations which have been detailed in the preceding section place it beyond a doubt that the electricity generated in our atmosphere is identical with that which is developed by friction. Philosophers, however, have sought to establish their similarity as chemical agents. M. Bonjol, for example, has decomposed water by means of the electricity of the air collected by an insulated pointed rod, in stormy states of the atmosphere; and the late unfortunate Mr Alexander Barry, who lost his life in the cause of science, succeeded in August 1824 in decomposing a solution of sulphate of soda coloured with syrup of violets. Bubbles of hydrogen appeared in the tube connected with the string of the electrical kite, while bubbles of oxygen appeared in the tube connected with the ground. In about ten minutes the blue liquid in the first tube became green from the separation of the soda, while the sulphuric acid, by passing to the pole in the other tube, changed its contents, as usual, red. See page 632.

CHAP. III.—ON THE CHANGES PRODUCED BY ELECTRICITY ON ORGANIC AND INORGANIC BODIES.

Changes produced by electricity.

That electricity is a powerful agent in the material world, has long been the opinion of those who have studied its effects. We have clearly seen that it performs a distinguished part in the economy of our atmosphere; but there is reason to believe that its agency is still more general, and that it exercises an influence almost universal over the laws of inorganic matter, as well as over the functions of organic life. Our knowledge, however, on these subjects is but in its infancy; and though the following sections will present to the reader many interesting and important phenomena, he will not fail to deduce from them the conclusion, that a wide field of discovery is yet unexplored, and that there is no branch of science more likely to reward the diligence of the young philosopher than that which treats of the agency of the electric fluid in animal and vegetable life, its effects upon inorganic matter, and its connection with the imponderable agents of light and heat. The general effects of electrical action may be comprehended under the following heads:

Phenon na an Laws

1. On the mechanical changes produced by electricity on inorganic bodies.
2. On the chemical changes produced by electricity on inorganic bodies.
3. On the changes produced by electricity on phosphorescent bodies.
4. On the changes produced by electricity on odoriferous bodies.
5. On the magnetic effects of electricity.
6. On the effects of electricity on animal bodies.
7. On the effects of electricity on vegetable bodies.

SECT. I.—*On the Mechanical Changes produced by Electricity on Inorganic Bodies.*

Mechan cal effe of electr city.

Although we know nothing of the real nature of the electric principle, yet, from its properties and effects, it has been found convenient to speak of it as a fluid. Its action upon bodies which either obstruct its motion, or afford it a ready passage, renders its analogy with a fluid still more striking, and we are thus enabled to comprehend phenomena which it would otherwise be more difficult to understand. A canal with a smooth bottom and sides may be considered as a good conductor of the aqueous fluid, and a river with a rocky bed and a tortuous course may be regarded as a bad conductor. Small quantities of water turned into each of these conductors will find its way by a slow movement, without injuring the surfaces over which it flows, just as a small or a large wire will carry off small quantities of electricity without suffering any mechanical change. But when the current of water is deep and strong, it will overcome its obstructions, burst its barriers, and destroy the channel which at first confined it; while the same current running with the same velocity in a smoother bed will make its way without producing any change upon the materials over which it runs; in the same manner as a small metallic wire will sometimes be expanded and sometimes burst in pieces when it transmits with difficulty an electric discharge, whereas the same discharge will find an unobstructed passage through a wire of still greater diameter.

Expans

The influence of electricity in expanding solid bodies was discovered by Dr Priestley during his experiments on the effects of explosion through metallic substances, when he found that a chain *was actually shortened* after the charge of a battery had been sent through it. A length of chain of exactly twenty-eight inches, after having transmitted a charge of sixty-four square feet of coated glass, was shortened one fourth of an inch, or $\frac{1}{256}$th part of the whole.

Mr Nairne found that a piece of hard drawn iron wire, ten inches long and $\frac{1}{100}$th of an inch in diameter, after receiving many times in succession a discharge of twenty-six feet of coated glass (or nine jars), was shortened $\frac{5}{40}$ths of an inch, or $\frac{1}{133}$d of an inch, by such discharge. Its length was examined after the sixth, ninth, and fifteenth discharges. The total contraction of the wire was fully one inch and one tenth, or *one ninth of the whole length.*

Mr Brooke obtained a contraction still higher than this, by passing a charge of nine bottles or sixteen feet of coated surface nine times in succession through a steel wire twelve inches long and $\frac{1}{100}$th of an inch in diameter. The wire was shortened *one inch and a half,* or *one eighth of its whole length.*

If the wire, however, through which the shock is passed nome- and aws ansion.

has suspended to it a weight so as to stretch it considerably, the wire will be increased in length, in place of being diminished. This effect is by no means inconsistent with those already described. The heat, which, as we shall afterwards see, is always evolved during the transmission of an electric charge, produces a softness short of fluidity, which allows the extending force to overcome the absolute tenacity of the wire.

It is very obvious that the contraction of the wire in one dimension in these experiments was owing to its expansion in a direction at right angles to the length, in the same manner as a piece of caoutchoue extended in one direction is shortened in the other. Mr Nairne indeed observed that the wire had increased in thickness; but though he used a pair of scales which turned with one eighth of a grain, he could not observe any change in the weight of the wire.

The same phenomenon takes place in fluid metals. If, for example, we fill a capillary or thermometer tube with mercury, and transmit through the mercurial column an electrical charge, the metal will suffer such a degree of expansion as to burst the tube to pieces.

When the body which transmits the shock has a less conducting power than metals, the tendency to expand will of course be still greater. If a little water, for example, is placed in a glass tube, and a shock passed through the water, the tube will burst by the expansion of the fluid; and the experiment will succeed even if a common drinking glass is filled with water and substituted for the tube. Beccaria placed a drop of water in the centre of a solid glass-ball, and burst the ball by transmitting a shock through the fluid drop. This experiment was beautifully varied by the Italian philosopher, who constructed a small mortar, and having put a ball into it, he placed behind the ball a drop of water, so as to lie between the two wires which passed through the side of the mortar. When an electric charge was sent through the two wires, the expansion sustained by the water drove out the ball with great velocity. M. Lullin gave the ball a still greater impulsion by substituting a drop of oil for the drop of water.

Even when the conductor is air, a violent expansive effect is created during the transmission of the electric shock. This effect is well shown by fitting a cork cap into an ivory mortar having a cavity an inch deep and half an inch wide. When a shock is sent through the wire in this cavity, it is expanded so suddenly as to drive out the cork with great violence.

When the electric shock is made to pass through solid bodies which are imperfect conductors, such as wood, stone, sugar, and glass, they will be broken by the expansion which is produced. In the case of glass not very thick, it will be broken into innumerable pieces. When the glass is so thick as to resist the shock, it is marked with vivid prismatic colours, which Mr Henley supposes to be thin laminæ of the glass separated from one another by the shock.

The expansive effect created by the shock is finely exhibited by dipping a clean brass chain in melted rosin, and laying it upon paper. If the charge of thirty-two square feet of coated glass is sent through it, the resinous coating will be driven off from every part of the chain, which will be entirely cleared of it.

When a clean uncoated brass chain is laid upon a plate of glass, and a charge of thirty-two square feet passed through it, the glass will be marked in every part of its surface where it was touched by the chain, every marking having the width and colour of the link. The metal could be scraped off the glass at the outside of the mark, but it was actually driven in other places into the pores of the glass. Dr Priestley, who made this interesting experiment, produced a similar effect upon glass with a silver chain, and small pieces of other metals.

Phenomena and Laws.

Diffusion of metals into vapour.

The reader who has perused with attention our chapter on Electric Light, will recognise in these experiments the origin of those beautiful results which have been obtained by Fusinieri, by passing the electric shock from a metallic ball to a polished metallic surface; and the diffusion of solid bodies into metallic vapour, as it may be called, is finely illustrated in the following experiments. Take three strips of window glass, each about three inches long and one wide, and having placed two narrow strips of gold leaf or leaf brass between them, so that the ends of the gold leaf project a little beyond the glass, transmit the charge of a large Leyden jar through the gold leaf. The gold leaf will be found to be melted by the shock, and driven into the surface of the glass. The outer plates of glass are generally broken in this experiment, and the middle one, which frequently remains entire, has an indelible metallic stain upon each of its surfaces. This stain is obviously the metallic vapour of the gold driven into the pores of the glass.

The dispersion of gold or silver into a metallic vapour may be exhibited in another manner. Let a strip of gold or silver leaf, or Dutch metal, be fixed with gum to the surface of a piece of paper, and be placed in such a manner between the forceps of an universal discharger, that a strong electrical charge may be passed through it. The metallic strip will entirely disappear, in consequence of having been dispersed into a vapour or powder, part of which remains in a state of oxidation on the paper, which, from this cause, receives a greenish-brown tinge.

The metallic colours thus obtained have been employed for impressing ornamental figures upon paper or silk. In order to do this, trace the outline of the figures on thick drawing paper, and having cut it out as in stincil plates, place it on the silk or paper intended to be ornamented. When a gold leaf is laid upon it, and a card above the gold leaf, the whole is placed in a press or beneath a weight, and an electrical charge sent through it; the metallic stain is limited to the portion of the drawing paper that is cut away, and consequently any outline figure may be readily impressed upon the ground employed to receive it.

Dr Franklin was the first person who impressed metallic stains upon glass by electrical discharges. Fine gold communicated a reddish stain and silver a greenish one, and the metallic vapour, when driven into the pores of glass, was able to resist the action of the strongest aqua regia.

Sect. II.—*On the Chemical Changes produced by Electricity on Inorganic Bodies.*

Chemical changes produced by electricity.

The effects of electricity as a chemical agent are strikingly displayed in its power of evolving heat, and consequently of inflaming and fusing bodies, and its power of promoting chemical composition and decomposition. The influence of electricity in producing combustion may be shown by several beautiful experiments.

Evolution of heat.

Exp. 1. *To light a candle by electricity.* Having wrapped some loose cotton wool round the extremity of a long brass pin or wire, roll the cotton in the powder of white or yellow rosin. Bring the naked end of the wire into contact with the external coating, while the cotton end is applied to the brass knob of a charged jar, and the rosin and cotton will be instantly inflamed.

By dipping the cotton in oil of turpentine, and using a large jar, the cotton may be inflamed in a similar manner; and its inflammation will be promoted by strewing upon it some fine brass dust.

Exp. 2. *To light a candle in another way.* Thrust a wire up through the middle of the candle to within a short distance of the wick, and having connected the outside coating of a charged jar, by means of a chain, with the lower end of the wire, touch the wick with the knob of the jar, and the candle will be lighted.

Inflammation of bodies.

Exp. 3. *To inflame phosphorus, &c.* Having placed powdered phosphorus, rosin, or camphor, on some cotton wool, and wrapped it round one of the knobs of a discharging rod, apply the knob thus covered to the ball of a charged jar, and the naked knob to the external coating of the jar, and the powder will be set on fire.

Powdered rosin floating on water may be set on fire by transmitting a charge over the surface of the water between two points.

Exp. 4. *To inflame alcohol or ether.* The alcohol or ether being placed in an insulated metallic cup, electrify the cup, and upon taking a spark from the cup either with the knuckle or any other conductor, the fluid will be set on fire.

If ether is placed in a thin stratum upon the surface of water, in a clean wine glass, a spark taken from the surface will inflame the ether when the water is connected with the prime conductor.

Exp. 5. *To inflame gunpowder.* Upon the end of an insulated metallic wire fix a small cartridge, and when the cartridge is presented to the knob of a charged jar, the powder which it contains will be exploded.

Exp. 6. *To exhibit the heat evolved by electricity.* Take a wooden rod, for example one of red fir, about one inch thick and ten inches long, and place it between the ball of the conductor and the conducting wire; put the ball of a thermometer in a hole bored in the wood, and in a few minutes the mercury will rise to about 112°. Van Marum, who made this experiment, found that in three minutes the mercury rose from 61° to 88°, and in five minutes to 112°.

Mr Snow Harris's instrument for measuring the evolution of heat.

Plate CCXIV. Fig. 1, 2.

The evolution of heat by electricity is finely shown by means of a beautiful and delicate instrument constructed by Mr Snow Harris. Mr Children and other philosophers had deduced from a variety of facts that the heat evolved by a metallic wire while transmitting an electric charge, is in some inverse ratio of its conducting power; and hence Mr Harris was desirous of measuring the relative degrees of heat so evolved by various metals and alloys in a gaseous medium such as air, and thus to discover their precise relations as conductors of electricity. The instrument which he used for this purpose is represented in Plate CCXIV. fig 1, and is little more than an air thermometer, the metallic wire to be examined being made to pass air-tight through the ball. A glass tube CDA, whose bore is regular, and somewhat less than one tenth of an inch, has one of its extremities DA bent upwards and outwards for about two inches, and is united by welding to a spherical reservoir A, containing a coloured fluid.[1] This tube is fixed to a correctly divided scale E, supported by a suitable base; and the *zero* of the scale is at *o*, on a level with the coloured fluid in the reservoir A. Above the reservoir A is screwed air-tight, by means of brass caps closely cemented, a glass ball B, three inches in diameter; and through this ball a metallic wire *m*, *n*, varying from $\frac{1}{100}$th to $\frac{1}{5}$th of an inch in diameter, may be passed air-tight by means of small flanges of brass *m*, *n*, fig 2, cemented in and round two holes drilled through the ends, each flanch having a small projecting shoulder to receive the wire, and upon which are screwed two brass balls *a*, *b*, so as to render the whole air-tight. In order to fix the wire, the brass parts are made quite clean internally, and the wire being passed directly through them, is gently stretched, and then compressed in the holes by small pegs of tough wood, so as to insure a good contact. The pegs and the wire are allowed to project a little, to enable the observer to substitute different wires expeditiously. When an electrical explosion of sufficient force is now made to traverse the wire *m*, *n* in the ball B, the heat which it evolves will be made evident by the ascent of the coloured fluid along the scale E.

Mr Harris now submitted to examination equal wires of different metals; and in order to insure the transmission of equal and similar explosions through each of them, he adopted the following contrivance. Two equal brass balls were fixed at a given distance, as in Lane's discharging electrometer. One of them, which was insulated, was placed in immediate connection with the positive side of the battery, while the other was connected with the negative side; the metallic wire to be examined forming part of the circuit. This last connection was made by means of two fixed copper wires inserted into the balls on each side of the glass, and made perfect at the points of junction. When the charge therefore of the battery was sufficiently intense to pass the given interval, the discharge took place through the wire in the ball. Mr Harris used a battery of *five* jars, each containing *five* square feet of coated surface. They were placed on a metallic base communicating with the negative conductor, and were charged by means of long copper rods projecting immediately from the bottom of each jar. The machine employed was a plate one, with a disc of glass three feet in diameter.

Mr Sn Harris' experi- ments the evo tion of h by elec city.

The results which Mr Harris obtained from an extensive series of experiments are given in the following table.

	Metals.	Effects.		Metals.	Effects.
	Copper	6	Alloys.	Copper 1 part, silver 1 part	6
	Silver	6		Copper 1 part, silver 3 parts	6
	Gold	9		Copper 3 parts, silver 1 part	6
	Zinc	18	Alloys.	Gold 1 part, silver 1 part	20
	Platinum	30		Gold 1 part, silver 3 parts	15
	Iron	30		Gold 3 parts, silver 1 part	25
	Tin	36	Alloys.	Tin 1 part, lead 1 part	54
	Lead	72		Tin 3 parts, lead 1 part	45
	Brass	18		Tin 1 part, lead 3 parts	63
Alloys.	Gold 1 part, copper 1 part	20	Alloys.	Tin 1 part, zinc 1 part	27
	Gold 3 parts, copper 1 part	25		Tin 3 parts, zinc 1 part	32
	Gold 1 part, copper 3 parts	15		Copper 8 parts, tin 1 part	18

Considering the heat to be in the inverse ratio of the conducting power, it appears from this table, 1*st*, That the heats evolved from silver and copper are alike, and also those from iron and platinum, and from zinc and brass,

---

[1] This fluid may consist of rectified alcohol, *one* part distilled water, *three* parts coloured tincture of cochineal, with a little sulphuric acid to make the whole sour.

nome-
a and
aws.

while the heats evolved from lead and tin are as 2:1; and from zinc and gold, and from brass and gold, as 2:1. 2*dly*, That silver and copper being regarded as the *best* conductors, from being the *least* heated by the explosion, the conducting power of

Gold to copper will be as 2: 3
Zinc or brass to copper or silver.......1: 3
Platinum or iron to copper or silver..1: 5
Tin to copper or silver...................1: 6
Lead to copper or silver.................1: 12

3*dly*, That the conducting power of an alloy of *gold* and *copper*, or gold and silver, is less than either metal separately; and that the difference in the conducting power increases with the quantity of the inferior conductor alloyed; and that tin and lead in alloy have a conducting power equal to the mean of their two separate conducting powers. And, 4*thly*, that copper alloyed with an eighth part of its weight of tin becomes as much heated by an electrical explosion as iron.

sion of
tallic
es.

Many beautiful experiments have been made by different philosophers, on the fusion of metallic wires. Mr Kinnersley, in the presence of Dr Franklin, transmitted the charge of a case of bottles through a fine iron wire. After first appearing red hot, the wire was melted into spherical drops like small shot. With a battery of thirty-two square feet, Dr Priestley melted into globules wires even so large as the seventieth of an inch in diameter, sometimes placing them in tubes of glass, and sometimes in paper. The most complete experiments, however, on the fusion of wires were made by Mr Brooke, Van Marum, Baron Kienmayer, Mr Cuthbertson, and Mr Singer. The following are a selection from their most successful experiments.

No. of Bottles.	Square Feet of Coated Surface.	Grains of Repulsion in Brooke's Electrometer.	Length of Wire.	Diameter of Wire.	Effect produced.
9	16	32	12	$\frac{1}{170}$	Steel wire melted.
9	16	32	12	$\frac{1}{170}$	Brass ditto ditto.
4		30	3	$\frac{1}{170}$	Steel ditto ditto.
2		45	1	$\frac{1}{170}$	Steel wire not ditto.
	48	4	3	$\frac{1}{170}$	Steel wire melted.
	48	15	6	$\frac{1}{150}$	Lead ditto ditto.
	40		18	$\frac{1}{250}$	Iron ditto ditto.
15 jars			60	$\frac{1}{150}$	Iron ditto ditto.

The last of these experiments was made by Mr Cuthbertson, and the last but one by Mr Singer. Mr Singer found that the power of any coated surface to melt wires varies with the thickness of the jars; which confirms the conclusion of Mr Cavendish, that the quantity of electricity necessary to charge different jars of the same extent of coated surface is inversely as the thickness of the jars.

r Sin-
r's expe-
nents.

"The effects of gradually increasing the power of the charge," says Mr Singer, "when wires of the same length and diameter are employed, are very remarkable. If the wire be iron or steel, its colour is first changed to *yellow*, then (by an increased charge) *blue*, by a further increase it becomes *red hot*, then red hot and *fused into balls;* if we continue to increase the charge, it becomes red hot and *drops into balls*, then *disperses in a shower of balls*, and lastly disappears with a bright flash, producing an apparent smoke, which, if collected, is a very fine powder, weighing more than the metal employed, and consisting of it and a portion of the oxygen of the atmosphere, with which it has combined."

The experiments of Van Marum were made with a much greater extent of coated surface, and the effects produced were consequently much more intense. The following are a few of his results:

Phenomena and Laws.

Van Marum's experiments.

Square Feet of Coated Surface.	Length of the Wire.	Diameter in parts of an inch.	Effect produced.
130	180 inches	$\frac{1}{151}$	Iron wire melted.
130	300	$\frac{1}{240}$	Iron ditto ditto.
225	120	$\frac{1}{38}$	Lead ditto ditto.
225	120	$\frac{1}{38}$	Tin ditto ditto.
225	5	$\frac{1}{38}$	Iron ditto ditto.
225	3·5	$\frac{1}{38}$	Gold ditto ditto.
225	0·25	$\frac{1}{38}$	Silver ditto ditto.
225	0·25	$\frac{1}{38}$	Copper ditto ditto.
225	0·25	$\frac{1}{38}$	Brass ditto ditto.

In the course of these experiments Van Marum observed the curious fact, that when a charge of 225 square feet of coated surface was transmitted through fifty feet of iron wire, *the jars were not entirely discharged*, and the residual charge was capable of melting two feet of the same wire.

With the view of determining the relative fusibility of different metals, Van Marum applied the same electrical charge to wires of different metals drawn to the same diameter. The following were the results with wires the 32d of an inch in diameter.

Metals.	Length of Wire Fused.
Lead	120 inches.
Tin	120
Iron	5
Gold	$3\frac{1}{2}$
Silver	$\frac{1}{4}$
Brass	$\frac{1}{4}$
Copper	$\frac{1}{4}$

Hence he concludes that lead and tin are the worst metals for conductors, and copper, brass, and silver, the best.

Cavallo's experiments.

M. Cavallo made some interesting experiments on the fusion of grains of native platinum by means of electricity. He placed the grains in a groove one tenth of an inch deep, cut in the surface of a cake of wax. A battery was discharged through a line of metallic grains thus arranged, and in this way they were partially but decidedly fused. He found the whiter grains to be more easily fused than those of a dark-grey colour.

Oxidation of metals.

Another of the chemical effects of electricity is its power of promoting the combination of metals with oxygen, or, what is the same thing, of oxidating them. Beccaria and others had observed this property of electrical action, but it is to Mr Cuthbertson and Mr Singer that we owe the most complete series of experiments on this subject. The apparatus used by Mr Cuthbertson is represented in Plate CCXIII. fig. 5, where AB is a cylinder of glass two inches and a half in diameter and eight inches high. A brass cap is screwed on the lower brass cap B, and in the interior of the vessel is fixed a small roller CD, on which is coiled a quantity of wire attached to a pack-thread at intervals of four inches. Into the centre of the upper cap A is screwed a brass tube F, about three inches long; the end of the pack-thread and wire is pushed through it by means of a long needle, and hog's lard is placed in the tube so that the thread and wire may move through it air-tight. By this means the wire is stretched along the axis of the glass cylinder, and when one length of it is exploded, another is drawn forward by the contiguous pack-thread, without opening the cylinder. The quantity of air absorbed in the process is indicated by a gage. It consists of a glass tube, about ten inches long, screwed into the lower end of the stop-cock, and plunged in a vessel of

Mr Cuthbertson's apparatus. Plate CCXIII. Fig. 5.

Phenomena and Laws.

quicksilver, the rise of which, when the stop-cock is opened, will be a measure of the air absorbed. Mr Cuthbertson found that the air was always deprived of a portion of its oxygen. When hydrogen or nitrogen was used in place of atmospheric air, no oxidation took place in the wire, and the wire was melted and minutely divided. The results obtained by Mr Cuthbertson are given in the following table, each wire being ten inches long.

Mr Cuthbertson's experiments.

Metals.	Diameter of Wire.	Charge in Grains of Cuthbertson's Electrometer.	Colour of the Oxide when collected.
Lead	$\frac{1}{90}$	20	Light grey.
Tin	$\frac{1}{90}$	20	Nearly white.
Zinc	$\frac{1}{90}$	45	Nearly white.
Iron	$\frac{1}{150}$	35	Reddish brown.
Copper	$\frac{1}{150}$	35	Purple brown.
Platina	$\frac{1}{150}$	35	Black.
Silver	$\frac{1}{150}$	40	Black.
Gold	$\frac{1}{150}$	40	Brownish purple.

Mr Singer's experiments.

Mr Singer repeated these experiments with shorter and finer wires, and with a moderate electrical charge. The wires were not placed in receivers, but stretched parallel to the surface of a sheet of paper, at the distance of one eighth of an inch. The following were his results with wires five inches long.

Metals.	Diameters of Wire.	Charge in Grains of Cuthbertson's Electrometer.	Colours of the Figures on Paper.
Lead	$\frac{1}{180}$	12	Brown and blue grey.
Tin	$\frac{1}{180}$	11	Yellow and grey.
Zinc	$\frac{1}{180}$	17	Dark brown.
Iron	$\frac{1}{180}$	12	Light brown.
Copper	$\frac{1}{160}$	12	Green, yellow, and brown.
Platina	$\frac{1}{180}$	13	Grey and light brown.
Silver	$\frac{1}{160}$	18	Grey, brown, and green.
Gold	$\frac{1}{180}$	18	Purple and brown.

When Mr Singer made the explosion over glass, he found that a portion of the metal appeared immediately under the wire in an unoxidated state, while the oxidated portion produced round the other a figure of some width. The figures are in this way more beautiful, though less permanent, than when they are produced upon paper.

Dr Wollaston's experiments.

The oxidating power of common electricity is finely exhibited in the following experiment, given by Dr Wollaston. Having coloured a card in a strong infusion of litmus, a current of electric sparks was passed along it by means of two fine gold points, which touched the card at the distance of an inch from each other. After a very few turns of the machine, and when the card was nearly dry, a *redness* at the place of the positive wire was distinctly manifest to the naked eye; and when the experiment was repeated with the negative wire on the same spot, it was restored to its original *blue* colour.

Revival of metallic oxides.

The metallic oxides may be revived, or restored to the metallic state, by means of electricity. Beccaria, who discovered this property, revived the oxide of zinc, and produced quicksilver from cinnabar by exploding a jar between two pieces of the calces. The following method of making this interesting experiment is given by Mr Singer. Introduce into a glass tube some oxide of tin, so that the oxide may cover about half an inch of the lower internal surface of the tube when it is laid horizontally. Place the tube on the table of Henley's discharger, and introduce the pointed wires into its opposite ends, that the oxide may lie between them. When several strong charges have been sent through the tube, a part of the tube will soon be stained with metallic tin, which has been revived by the transmitted electricity. The charge of a very moderate-sized jar is sufficient to revive the mercury and sulphur which compose vermilion.

Phenon
na and
Laws.

Deoxid
ing pow
of negat
electrici

The deoxidating power of negative electricity is well illustrated by the following elegant experiment of Dr Wollaston's. Having coated with wax about two or three inches of the middle of a fine silver wire, the hundred and twentieth of an inch in diameter, he cut the wire through in the middle of the wax, so as to expose a section of it. The two coated extremities of the divided wire were plunged in a solution of sulphate of copper, placed in an electric circuit between the two conductors, and sparks taken at the distance of one tenth of an inch were passed through the solution. After a hundred turns of the machine, the wire communicating with the negative conductor had a precipitate formed upon its surface, which by burnishing was clearly copper, whereas there was no such coating upon the other wire. The direction of the electric current being reversed, the order of the phenomena was reversed, and the copper was shortly re-dissolved by the aid of the oxidating power of common electricity, and a similar precipitate formed upon the opposite wire. Dr Wollaston obtained similar results from gold wires and a solution of corrosive sublimate.

Influen
of electi
city in c
mical co
position
and dec
position

The influence of electricity in effecting chemical composition and decomposition forms one of the most interesting departments of electrical and chemical science. The most valuable researches which have been made on this subject were carried on by means of the Voltaic battery, and must necessarily be detailed under another article; but the discoveries which were made through the agency of the electrical machine fall to be recorded in the present section.

Experi-
ments c
Mr Wa
tire.

One of the earliest experiments on the influence of electricity as a powerful chemical agent, was made by Mr Warltire, who fired a mixture of atmospheric air and hydrogen gas by means of electricity in a close copper vessel containing about three pints. Although no air could escape by the explosion, yet a loss of two grains was perceived in every experiment. When the vessel which contained the gases was clean and dry, a dewy moisture was found adhering to the inside of the vessel. Guided by this indication, Dr Priestley entered upon the subject. Having placed a blue solution of water and litmus in a glass tube, he transmitted through it a current of electrical sparks from a brass wire. In two or three minutes the blue liquor became red, particularly at the part where the sparks entered, and the air inclosed in the tube was diminished. The appearance of an acid having been formed at the expense of the air confined in the tube, induced Dr Priestley to place the tube in the receiver of an air-pump, so that by gradually exhausting the air, the part of it inclosed in the tube expanded and pushed out the discoloured liquor. Upon again admitting the air, a new portion of the litmus solution was introduced, while the confined air remained the same as before, and resumed the space which it had occupied after the passage of the electric current. After this the electrical sparks were no longer able to alter the colour of the solution, or to cause any decrease in the volume of the confined air.

Of Dr
Priestle

In passing a current of electric sparks through olive oil, turpentine, oil of mint, and ether, Dr Priestley found that an inflammable gas was evolved.

In his experiments on the gases Dr Priestley was more successful in transmitting the spark through ammoniacal ome- and ws.

gas; he found that two hundred shocks passed through a given quantity of the gas produced an increase of volume equal to one fourth of the whole. Upon subsequently admitting water, the original quantity operated upon was absorbed, and the remaining gas, equivalent to the expansion effected by the electric shocks, was found highly inflammable.

Dr Priestley likewise passed an electrical current, consisting of slight shocks continued for about an hour, through an inch of carbonic acid gas confined in a glass tube one tenth of an inch in diameter, when, upon admitting the water, one fourth part only was absorbed. In a similar manner Dr Priestley succeeded in decomposing carburetted hydrogen, the charcoal being deposited in a pulverulent form on the interior of the tube. When a succession of electric sparks from a moderate-sized conductor during the space of five minutes had failed in effecting this decomposition, he found that two shocks of a jar, each of which might be produced in less than a quarter of a minute with the same machine in the same state, were sufficient to cover the whole of the inside of the tube with the black carbonaceous matter. Dr Priestley remarked in these experiments that no shock, however powerful, would decompose the gas, if the quantity operated upon were great.

eri- ts of Hon. Ca- lish.

The power of electricity as a chemical agent was studied with peculiar success by the Honourable Mr Cavendish. In the year 1781 he fired 500,000 measures of hydrogen with about two and a half times that quantity of atmospheric air, and having by this means obtained a hundred and thirty-five grains of pure water, he was led to the conclusion that water was composed of two gases, viz. oxygen and hydrogen. In pursuing these enquiries Mr Cavendish made use of the apparatus shown in fig. 6 of Plate CCXIII. The air to be examined was confined in a bent glass tube A, filled with mercury, and having its ends immersed each in a vessel of the same fluid. The air to be electrified was introduced by a piece of glass tube ABC, fig. 7. In order to use this apparatus, the tube ABC being filled with mercury, is introduced as in fig. 7, with its bent extremity uppermost, into the vessel containing the gas, and standing in the pneumatic trough. In this part of the process the orifice at C is stopped by a finger, by withdrawing which a little mercury will descend through C, and an equal volume of the gas will enter at the end A. When the gas has been admitted in sufficient quantity into the tube ABC, it is withdrawn and reversed, the end C, which is placed uppermost, remaining carefully closed. The extremity A, which fits the end of the tube in fig. 6, is introduced beneath the mercury in either of the glasses, and by withdrawing the finger from the upper end C of the transferring tube, the mercury will descend, and the gas will be forced into the tube A, fig. 6. The orifice of the transferring tube should not be greater than that of a common thermometer tube.

In order to introduce portions of air successively during the same experiment, Mr Cavendish used a tube AB of a small bore (see fig. 8), a bulb C, and a tube DE, having a bore larger than that of AB. This apparatus having been first filled with mercury, the bulb C and tube AB are filled with the gas, by introducing the end A beneath the inverted jar, upon the shelf of the pneumatic trough, and then drawing the mercury from the leg D by means of a syphon. The aperture A being closed, the apparatus is weighed. The extremity A, fig. 8, is then fitted into the end of the tube A, fig. 6. When it is required to force air out of this apparatus into the tube, a wooden cylinder with a tight fitting is thrust down into the tube ED, an additional quantity of mercury being occasionally poured in at E to supply the place of what is forced into the bulb C. When the experiment is completed the apparatus is again weighed. The increase of weight is due to the mercury introduced, and its volume is equal to that of the air transferred to the tube A, fig. 6. The bore of the tube A was generally one tenth of an inch in diameter, and the aerial column in the bend of the tube from one half to three fourths of an inch.

Phenomena and Laws.

In transmitting the electric spark through this tube, Mr Cavendish, instead of making one end of it communicate with a conductor, placed an insulated ball at such a distance from the conductor as to receive a spark from it, and made a communication between that ball and the mercury in one of the glasses, the mercury in the other glass communicating freely with the ground.

In transmitting the electric spark through common air in contact with a blue aqueous solution of litmus, a red tint was produced in the solution. When lime-water was inclosed in the tube instead of litmus, and sparks transmitted till there was no further diminution in the volume of the included air, no cloudiness appeared in the lime-water, and the diminution of volume, amounting to one third of the original bulk of the air, exceeded the diminution from deoxidation alone, which would have been only one fifth.

When this experiment was repeated with some impure oxygen gas, a considerable diminution of volume was produced, but there was no cloudiness in the lime-water, and none could be perceived by adding to it a little carbonic acid gas; a small portion of caustic ammonia, however, produced a brown precipitate. Hence it is obvious that the lime-water was saturated with some acid formed in the process.

Having inclosed in the tube some of the same impure oxygen in contact with soap leys, the diminution of volume proceeded faster than with the lime-water, the greater strength of the alkaline lixivium acting as a more powerful absorbent of the acid which was generated.

When pure oxygen or pure azote was used no absorption took place; but when five volumes of pure oxygen were mixed with three of common air, the absorption was almost total; and as common air contains about one part of oxygen and four of azote, the mixture of five parts of oxygen and three of common air was equivalent to seven parts of oxygen and three of azote.

Mr Cavendish now supplied the interior of the tube with a little alkaline ley, and having introduced a mixture of seven parts of oxygen and three of azote, he transmitted a current of electric sparks, admitting fresh gas as the volume of air diminished. When the diminution ceased, a little pure oxygen, and afterwards a little common air, were added, in order to see if the absorption ceased from any want of a proper proportion in the two elements. As this was not the case, the soap leys were separated from the mercury, and were found to have become perfectly neutral, from their having no effect on the colour of litmus. When the leys were evaporated a dry *nitrate of potash* was obtained. By repeating this experiment on a more extended scale, Mr Cavendish demonstrated that the soap leys had been converted into a solution of nitre, and therefore established the great truth that nitric acid had been formed during the process, and that nitric acid is a compound of oxygen and azote.

Apparatus and experiments of Van Marum.

By means of the great Teylerian electrical machine at Haerlem, Van Marum, Van Troostwyk, &c. made many experiments on the chemical agency of electricity. The apparatus which they used, shown in Plate CCXIII. fig. 9, consists of a tube of glass DE, twelve inches long and a quarter of an inch in diameter, hermetically sealed, and having a gold or platina wire D*d* an inch and a half long fixed at D. Another platina wire E*e* was carried up from

Apparatus and experiments of Van Marum.

the open end of the tube E to *e*, within one eighth of an inch of the end *d* of the upper wire. The tube DE having been filled with distilled water, the open end of it E was immersed in a vessel V containing quicksilver, and the upper end D of the wire D*d* was brought into contact with the insulated brass ball C, placed at a little distance from AB, the prime conductor of the electrical machine. The lower wire E*e*, immersed in quicksilver, communicated with a chain VG connected with the outer coating of a Leyden jar containing about a hundred and forty-four square inches of coated glass, and having its ball M in contact with the prime conductor AB. When the electrical discharges were sent through the distilled water, the gas was disengaged as long as the ball C was in contact with the conductor; but upon increasing its distance, a position was found where the gas was disengaged, and ascended to the top of the tube. The evolution of the gas continued till it reached nearly the lower extremity of the upper wire, and then a discharge caused the whole gas to disappear, its place being supplied by water. With this apparatus the Dutch philosophers made the following experiments.

Oxygen gas from red precipitate had its original volume diminished one twentieth, and the properties of what remained were not changed.

Nitrous gas had its volume diminished to less than one half. There were no red fumes when it was mixed with atmospheric air, neither was there any condensation. It would not support combustion, and it lost its usual smell. A kind of powder covered the surface of the mercury, consisting of a new combination formed from the mercury.

Hydrogen gas, obtained from sulphuric acid and iron, suffered no diminution. Owing probably to some admixture of common air, it gave a slight redness to tincture of turnsol.

Olefiant gas from sulphuric acid and alcohol had its original volume tripled, and in some degree lost its inflammability.

Sulphurous acid gas, from sulphuric acid and charcoal, had only one eighth of its volume absorbed by water. Black spots were formed on the inside of the glass receiver. It had little smell, and extinguished a candle.

Muriatic acid gas experienced a considerable diminution of volume, but the remainder was readily absorbed by water. The electric sparks would not pass through more than two inches and a quarter of this gas.

Carbonic acid gas from sulphuric acid and chalk had its volume increased a little, and was made less absorbable by water.

Ammoniacal gas had its volume at first almost doubled, and then experienced a slight diminution. It became incapable of being absorbed by water, and exploded by the contact of flame.

Fluoric acid gas experienced no perceptible change.

Atmospheric air gave a slight redness to tincture of turnsol, and at the same time became sensibly deoxygenated. The diminution of volume was $\frac{151}{500}$ths, the mean of three experiments; and of the same air not electrified $\frac{182}{500}$ths, the mean of three experiments.

The Dutch philosophers made many other experiments which we have not space to describe, and in 1789 they succeeded in repeating the experiment of Cavendish on the decomposition of water.

Dr Wollaston's experiments and apparatus.

Hitherto a powerful apparatus was deemed necessary for effecting the decomposition of water, and a succession of discharges from a coated surface was deemed indispensable. Dr Wollaston, however, considering that the decomposition must depend upon a proper proportion between the quantity of water and the decomposing force, conceived the idea of reducing the surface of communication between the air and the metal which conveyed the electricity.

"Having procured," says he, "a small wire of fine gold, and given it as fine a point as I could, I inserted it into a capillary glass tube; and after heating the tube so as to make it adhere to the point, and cover it in every part, I gradually ground it down till, with a pocket lens, I could discern that the point of the gold was exposed.

"The success of this method exceeded my expectations. I coated several wires in the same manner, and found that when sparks from the conductors before mentioned were made to pass through water by means of a point so guarded, a spark passing to the distance of one eighth of an inch would decompose water when the point exposed did not exceed one seven hundredth of an inch in diameter. With another point, which I estimated at $\frac{1}{15000}$th, a succession of sparks one twentieth of an inch in length afforded a current of small bubbles of air.

"I have since found that the same apparatus will decompose water with a wire one fortieth of an inch diameter, coated in the manner before described, if the spark from the prime conductor passes to the distance of four tenths of an inch of air.

"In order to try how far the strength of the electric spark might be reduced by proportional diminution of the extremity of the wire, I passed a solution of gold through a capillary tube, and, by heating the tube, expelled the acid. There remained a thin film of gold lining the inner surface of the tube, which, by melting the tube, was converted into a very fine thread of gold through the substance of the glass.

"When the extremity of this thread was made the medium of communication through water, I found that the mere current of electricity would occasion a stream of very small bubbles to rise from the extremity of the gold, although the wire by which it communicated with the positive or negative conductor was placed in absolute contact with them. Hence it appears that decomposition of water may take place by common electricity as well as by the electric pile, although no discernible sparks are produced. The appearance of two currents of air may also be imitated, by occasioning the electricity to pass by fine points of communication on both sides of the water; but in fact the resemblance is not complete, for in every way in which I have tried it, I observed that each wire gave both oxygen and hydrogen gas, instead of their being formed separately, as by the electric pile.

"I am inclined to attribute the difference in this respect to the greater intensity with which it is necessary to employ common electricity; for, that positive and negative electricity so created have each the same chemical power as they are observed to have in the electric pile, may be ascertained by other means."

The preceding experiment, which is only an elegant repetition of one formerly made by Dr Pearson and the Dutch philosophers, has excited much attention, and cannot be regarded as any proof of the identity of ordinary and Voltaic electricity; Dr Faraday justly remarks that it should never be quoted as establishing true electrochemical decomposition, because the law which regulates the transference and final place of the evolved bodies has no influence here. The water is decomposed at the two poles by an independent action, and the oxygen and hydrogen evolved are the elements of the water existing at the wires the instant before. The substitution of the finger for one of the points will not interfere with the action of the other. But although Dr Wollaston did not decompose water in any way analogous to that of the pile, yet Dr Faraday seems to have succeeded in doing it by the same apparatus; but when he considered that he had obtained the true effect, the gas evolved was so small in quantity that he could not ascertain whether or not oxygen was emitted at the one wire and hydrogen at the other, as ought to have been the case.

D Fara- s appa- s and eri- ts.

The inability of Dr Wollaston's apparatus to exhibit in an unquestionable manner true electro-chemical decomposition being thus obvious, Dr Faraday devised the following ingenious arrangement for effecting chemical decomposition by ordinary electricity, and by means of it he effected true electro-chemical decompositions, perfectly identical with those produced by Voltaic electricity. The plate machine which he used had its glass disc fifty inches in diameter. It had two sets of rubbers. The prime conductor consisted of two brass cylinders, connected by a third, the whole length being twelve feet, and the surface in contact with air was 1422 inches. When well excited, one revolution of the plate gives ten or twelve sparks, each an inch long; and sparks or flashes from ten to fourteen inches long may easily be drawn from the conductors. When moderately worked, each turn of the machine is made in four fifths of a second. The electric battery consists of fifteen equal jars, each twenty-three inches in circumference, and coated eight inches upward from the bottom, so as to contain 184 inches of glass each, coated on both sides, independent of the bottoms, which are thicker glass, and contain each about fifty square inches.

In order to carry off instantaneously electricity of the feeblest tension, Dr Faraday formed what he calls a *discharging train.* This discharging train consisted in connecting a sufficiently thick wire metallically, first with the metallic gas pipes of the house, then with the metal pipes of the public gas works of London, and lastly with the metallic water-pipes of London. This arrangement was so effectual that the electricity even of a single Voltaic trough was instantly carried off; and this was essential to the success of many of his experiments.

e XIV. 3.

The arrangement for applying the apparatus now described to chemical decomposition is shown in Plate CCXIV. fig. 3. Two pieces of tinfoil *a*, *b* are placed upon a glass plate raised above a piece of white paper to prevent the interference of shadows. One of these pieces, *a*, is connected by an insulated wire *c*, or by a wire and wet string, with the electric machine, and the other piece, *b*, by a wire *g*, with the discharging train or the negative conductor. Two pieces of fine platina wire must then be provided, bent as in fig. 4, so that the part *d* shall be nearly upright, whilst the whole rests on the three points *efp*. By this means we can obtain at pleasure surfaces of contact as minute as possible; the connection can be discontinued or removed in a moment, and the substances which are acted upon can be readily examined. With this apparatus Dr Faraday obtained the following results.

4.

1. Having made a coarse line on the glass plate with a solution of sulphate of copper, the ends *p* and *n* of the platina wires were put into it, the foil *a* being connected by a wire and wet string with the positive conductor of the machine, so that no sparks passed. After twenty turns of the machine there was so much copper precipitated on the end *p* that it looked like copper wire, no apparent change having taken place at *n*.

2. A large drop of a mixture of equal parts of muriatic acid and water coloured a deep blue by sulphate of indigo was placed on the glass, so that the ends *p* and *n* were plunged in opposite sides of it; *one* turn of the machine evolved sufficient chlorine to exhibit bleaching effects round *p*. *Twenty* revolutions produced no effect at *n*, but there was so much chlorine got free at *p*, that when the drop was stirred the whole became colourless.

3. Having mingled a solution of iodide of potassium with starch, the ends *p* and *n* were immersed in a drop of it as before; on turning the machine iodine was evolved at *p*, but not at *n*.

Dr Faraday's apparatus and experiments.

Dr Faraday improved his apparatus still further by wetting a piece of filtering paper in the solution to be examined, and placing it on the glass beneath the points *p*, *n*. The paper will retain the substance evolved at the point of evolution; its whiteness will render visible the least change of colour, and will allow the point of contact between it and the wires *p*, *n* to be contracted to the utmost degree. Dr Faraday found a piece of paper moistened in the solution of iodide of potassium and starch, or of the iodide alone, to be with certain precautions a most admirable test of electro-chemical action; and when it is placed and acted upon in the manner already described, it will exhibit the evolution of iodine at *p* by half a turn only of the machine. He found, indeed, that with these adjustments, and the use of iodide of potassium on paper, chemical action is sometimes a more delicate test of electrical currents than the most delicate galvanometer.

A piece of litmus paper wetted in a solution of muriate or sulphate of soda was quickly reddened at *p*, and a similar piece wetted in muriatic acid was soon bleached at *p*, no similar effects taking place at *n*.

A piece of turmeric paper wetted in a solution of sulphate of soda was reddened at *n* by two or three turns of the machine, and by twenty or thirty turns abundance of alkali was evolved at the same place. By turning the paper round so that the spot came under *p*, and working the machine, the alkali soon disappeared, the place became yellow, and a brown alkaline spot appeared in the new part under *n*.

Dr Faraday next combined a piece of turmeric paper with a piece of litmus, wetting both with a solution of sulphate of soda. The paper was placed so that *p* was on the litmus and *n* on the turmeric paper. By a few turns of the machine acid was evolved at *p* and alkali at *n*, as in galvanic decomposition. These various decompositions were equally effected whether the electricity passed to the foil *a* from the machine through water or wire only, by *contact* with the conductor, or by *sparks* there, provided the sparks were not so large as to cause the electricity to pass in sparks from *p* to *n*, or towards *n*.

Plate CCXIV. Fig. 5.

Dr Faraday's final experiment deserves peculiar notice, as affording a case in which there is the most perfect analogy between the effects of ordinary and Voltaic electricity. Three compound pieces of litmus and turmeric paper, when wetted by a solution of sulphate of soda, were disposed on a plate of glass as shown in fig. 5. The wire *m* was connected with the prime conductor, *t* with the discharging train, and the wires *r* and *s* connected the moistened pieces of paper, each wire resting on three points, one of the points, at *r* and *s*, being on the glass, and the others on the papers, the ends *p*, *p*, *p* resting on the litmus and *n*, *n*, *n* on the turmeric paper. When the machine had been worked for a short time, acid was evolved at all the poles *p*, *p*, *p*, by which the electricity entered the solution; and alkali at the other poles *n*, *n*, *n*, by which the electricity left the solution.

The precaution above referred to, in using the iodide of potassium as a test of electro-chemical action, is that no sparks should be passed in any part of the current, and no increase of intensity allowed by which the electricity may be induced to pass between the platina wires and the moistened papers, *otherwise than by conduction;* for if the electricity burst through the air, a different effect is produced. The litmus paper is in this case reddened by the spark, and iodine will be evolved from paper moistened by iodide of potassium. This effect is owing to the formation of nitric acid by the oxygen and nitrogen of the air. The acid thus formed reddens the litmus paper, or prevents the exhibition of alkali in the turmeric paper, or evolves iodine from the iodide of potassium. We have thus a simple and elegant method of illustrating Mr Cavendish's experiment of forming nitric acid from the atmosphere.

M. Bonjol's experiments.

M. Bonjol of Geneva has announced that he has decomposed water by common electricity. The electricity was obtained from an insulated lightning rod; and the decomposition is said to have proceeded continuously and rapidly even when the electricity of the atmosphere was by no means powerful. M. Bonjol is also said to have decomposed potash and chloride of silver, by passing the sparks of an ordinary machine through these substances placed in narrow tubes. Dr Faraday justly regards these as not cases of true electro-chemical decomposition, but as analogous to that of Dr Wollaston's apparatus, arising either from a very high temperature acting upon minute portions of matter, or perhaps connected with the results produced in air by the passage of the spark.

Experiments of Dr Barry.

One of the most remarkable decompositions, however, which has been obtained previous to Dr Faraday's experiments, is that of the late Mr Barry. This experiment is given as a proof of the chemical action of atmospheric electricity; but, as Dr Faraday has shown, it possesses a much greater interest if confirmed. The following is his own account of it:—"In August 1824 I elevated the kite in an atmosphere favourable to the exhibition of its phenomena. It was raised from an apparatus firmly fixed in the earth, and was insulated by a glass pillar. The usual shocks were felt on touching the string, which simple fact I am induced to mention from the circumstance of no electrometer having been employed. The portion of string let out, with a double gilt thread passed through it, was about 500 yards. I then made the connection shown in fig. 6, where the straight glass tubes, A, B, having platina wires passed from above half way down their axes, and standing in their respective glass cups C, D, were filled with a solution of sulphate of soda coloured with syrup of violets, connected also with each other by the bent glass tube E, likewise filled with the above solution in the usual manner. A portion of gilt thread *d* was then brought from the tube at A, and united to the kite-string K, whilst a similar thread *b* was carried from B to the earth. Bubbles of hydrogen in A, and of oxygen in B, soon appeared. In about ten minutes the blue liquid in A became green from the separation of the soda, whilst the sulphuric acid, by passing to the pole in the tube B, changed its contents, as usual, red.[1]

Fig. 6.

Dr Fara day's ob servatio on them

The effect now described as produced by *atmospheric electricity* was never produced by *common electricity.* Dr Wollaston and other philosophers could not obtain the gases in separate vessels, and Dr Faraday kept his powerful machine in action for a quarter of an hour, during which 700 revolutions were made, without producing any sensible effect, although the shocks that it could then have given must have been more numerous and powerful than could have been taken with any chance of safety from the kite-string of Mr Barry. Dr Faraday thinks "it just possible that the air which was passing by the kite and string, being in an electrical state sufficient to produce the 'usual shocks' only, could still, when the electricity was drawn off below, renew the charge, and so continue the current. The string was 1500 feet long, and contained two double threads; but when the enormous quantity which must have been thus collected is considered, the explanation seems very doubtful." Dr Faraday therefore considers Mr Barry's experiment as a very important one to repeat and verify; and he remarks, that if it is confirmed, it will be the first recorded case of the true electro-chemical decomposition of water by common electricity, and will supply a form of electrical current which is exactly intermediate, both in point of quantity and intensity, between those of the common electrical machine and the Voltaic pile.

Effects electric on gase

The effects of electricity on mixed and compound gases are exhibited in the following table, taken chiefly from Mr Singer's work on electricity.

Mixed Gases.	Results.
Atmospheric air and hydrogen,	Water and nitrogen.
100 oxygen and 200 hydrogen,	Water.
160 chlorine, 100 hydrogen,	200 muriatic acid gas.
Muriatic acid gas and oxygen,	Chlorine (and water)?
Carbonic oxide and oxygen,	Carbonic acid.
Nitrogen and oxygen,	Nitric acid.
Sulphurous acid and oxygen,	Sulphuric acid.
Phosphuretted hydrogen and oxygen,	Water and phosphoric acid.
Sulphuretted hydrogen and oxygen,	Water and sulphurous acid.
150 oxygen and 200 ammonia,	Water and 100 nitrogen.
100 olefiant gas and 284 oxygen,	Carbonic acid and water.
100 olefiant gas and 100 oxygen.	Carbonic oxide and hydrogen.
100 carburetted hydrogen and 100 oxygen,	Carbonic oxide and hydrogen.
100 carburetted hydrogen and 200 oxygen,	Carbonic acid (and water?)

Compound Gases.	Results.	
Muriatic acid,	Hydrogen	Messrs Henry and Dalton.
Fluoric acid,	Hydrogen	
Nitrous acid,	Nitric acid and nitrogen.	
Carbonic acid,	Carbonic oxide and oxygen.	
100 sulphuretted hydrogen,	Sulphur and 100 hydrogen.	
100 phosphuretted hydrogen,	Phosphorus and 100 hydrogen.	
100 ammonia,	150 hydrogen and 50 nitrogen.	
100 olefiant gas,	Carbon and 200 hydrogen.	
100 carburetted hydrogen,	Carbon and 200 hydrogen.	

---

[1] *Phil. Trans.* 1831, Part I. p. 165, 166.

The effects thus indicated are regarded by Mr Singer as mechanical, and as arising from the momentary agitation into which the various media are thrown by the action of the spark, which tends to promote a new arrangement of parts. This theory, of which Mr Singer himself not only saw, but has stated, the difficulties, cannot now be maintained with any show of reason; and there can be no doubt that the effects in question arise from a molecular polarity related to the two poles of the electric circuit, or to the two kinds of electricity which exist in nature.

fluence electri- y on pu- efaction d fer- entation.

It has been asserted, but not from any extensive series of accurate experiments, that putrefaction and fermentation are promoted by electricity. M. Achard of Berlin, considering that, in animals killed by lightning, the process of putrefaction advances with great rapidity, cut a piece of beef into three parts, and electrified one piece positively for ten hours, another negatively during the same time, while the third was not electrified at all. On the fourth day the electrified pieces had an intolerably fetid smell, while the unelectrified piece had only begun to smell a little. The same result was obtained with a piece of boiled veal. M. Achard also killed several birds by electrical shocks, and having killed others by sticking a needle through their heads, he placed them all under similar circumstances. The birds killed by electricity became putrid much sooner than the rest. The influence of electricity on fermentation was studied also by M. Achard. A handful of rye brought into a state of fermentation for the purpose of being distilled, was separated into two portions, one of which was electrified and the other not. Five hours afterwards the vinous fermentation had ceased in the electrified portion, but did not cease in the other portion till after the lapse of eight hours.

fluence electri- y on co- urs.

The influence of electricity upon colours is a subject of peculiar interest, and cannot fail to prove a rich field of discovery to those who may enter upon it with ardour. That electricity does alter the colour of particular bodies is undoubted; but whether it produces a real chemical change on these bodies, or merely a transient change in their power of absorbing specific rays of the spectrum, remains to be determined. The few experiments made by Cavallo are extremely vague and disparate. He found that vermilion, carmine, verdigris, white and red lead, had their colour altered by the electric shock; and that the colours of orpiment, gamboge, sage-green, red ink, ultramarine, Prussian blue, and of a few other compounds, were not altered. The eye, however, is no judge of a real change of colour. It can judge only of the general result of the change, without indicating the nature of the change or changes that have taken place. A body, too, which may have lost or gained the power of absorbing definite rays of the spectrum, may often appear to have suffered no change at all, provided that the sum of the changes is a colour similar to the original colour of the body.

In producing these effects, namely, putrefaction, fermentation, and change of colour, the electric fluid may act, not by any virtue of its own, but by the intermedium of those ponderable substances which the spark carries along with it, and consequently leaves in bodies.

Sect. III.—*On the Changes produced by Electricity on Phosphorescent Bodies.*

Influence of electricity on phosphorescence.

Although the phenomena of phosphorescence have been lately much studied, yet philosophers are very little acquainted with its cause, whether it is developed by the light of the sun, the action of heat, or the transmission of electricity.

Almost all bodies may be rendered luminous during the transmission of an electric discharge through their substance; but unless this luminosity continues after the discharge is over, the body cannot be said to have been rendered phosphorescent by electricity. In his numerous experiments on this subject, Mr Skrimshire invariably kept his eyes closed till the sound of the discharge had been heard, and therefore the light which he then saw was not the light of the electric spark, modified by its transmission through the body, but was a real phosphorescence, which continued after the original cause of it was withdrawn.

The substances which he submitted to examination were placed on a horizontal brass plate, fixed to the ball of the prime conductor, and he then tried to obtain a spark from the body by means of a common discharger. The body was next placed upon a table, and the charge of a Leyden phial passed *over it*, at the distance of about a quarter or half an inch above its surface; and, as a last trial, the charge of the jar was made to traverse its surface by resting the points of the discharging rod at an inch or more distant from each other, upon the specimens under examination.

The following table contains a general view of the results obtained by Mr Skrimshire:

esults tained Mr rim- ire.

Results obtained by Mr Skrimshire.

Table showing the Phosphorescent Effects of Electricity upon different Bodies, according to the Experiments of Mr Skrimshire junior.

CALCAREOUS GENUS.

Calcareous spar,	Rendered very luminous by the shock.
Common chalk,	Very luminous when the shock passed above it. When passed along its surface a zigzag track of light continued several minutes.
Ketton stone,	Part of the stone shattered, and its luminous grains dispersed in all directions.
Selenite,	Shines for a few seconds with a vivid greenish light.
Fresh nitrate of lime,	Gave small sparks, which were red flame-coloured upon its surface.
Muriate of lime,	More phosphorescent than the nitrate of lime.
Dark purple fluor spar,	Gave no sparks, but the electric fluid passed in a purple stream with a whizzing noise.
Yellowish fluor spar,	Gave very good sparks, while dark purple fluor spar gave none.
Sulphuret of lime, or Canton's phosphorus,	The most luminous of any substance by the electric explosion.
Phosphate of lime,	A minute red spark. It is inflammable by a very small shock.
Calcined oyster shells,	Are rendered beautifully luminous, and give the prismatic colours.
Ditto calcined with sulphur,	Give a durable and bright light, according to Mr Singer.

BARYTIC GENUS.

Carbonate of barytes,	No spark, but very luminous when the shock was passed above it.
Sulphate of barytes,	Good sparks, but slightly luminous. According to Singer, it gives a bright green light, more bright than that of the carbonate.
Sulphuret of barytes,	Was slightly luminous by the electric explosion.

Phenomena and Laws.

Results obtained by Mr Skrimshire.

MURIATIC GENUS.

Magnesia, pure and carbonated,	Were both transiently luminous by the electric explosion.
Sulphate of magnesia,	Very luminous through its whole substance.
Sulphuret of magnesia,	Not more luminous than the carbonate.
Chlorite,	Sparks branching off in minute party-coloured points.
Steatites, talc, and fibrous amianthus,	Gave sparks, and were slightly luminous by the explosion.
Asbestus,	Ramifications on its surface more variegated than in chlorite.
Mica,	Affords sparks, but is not luminous by the explosion.
Micaceous schistus,	Sparks ramified as in chlorite, scarcely phosphorescent.

ARGILLACEOUS GENUS.

Alum,	Spark purple, rather ramified, luminous through its whole surface.
Pipe clay,	Sparks, and luminous, but not luminous when made into pipes.
Slate clay,	Sparks, and luminous, but loses its absorbent power as it becomes bituminous.
Slates,	Sparks, and absorbed electric light from the explosion.
Hone stone,	Good spark, and phosphoric by the explosion.
Fullers' earth,	Good bright sparks, but slightly luminous.
Reddle,	No spark, but a purple stream attended with a very sharp hissing noise.
Armenian bole,	Ramified spark. It is not luminous by the explosion.
Basalt,	Sparks radiated upon its surface, but not ramified.
Bricks and tiles,	Small purple sparks of a bright red colour, slightly luminous.
Queen's ware,	Good spark, flame coloured and radiated upon its surface, but not phosphoric.
Ditto fractured,	The unglazed surface gives a purple spark, and is luminous by the explosion.

SILICEOUS GENUS.

Rock crystals,	Light, first red, and then white (*Singer*); all phosphoric (*Skrimshire*).
Quartz,	Phosphoric, with a dull white light; a purple stream instead of a spark.
Flints,	Small purple spark; not so luminous as quartz.
Lapis lazuli,	Affords very good sparks, and is luminous by the shock.
Agates, felspars, jaspers, Scotch pebbles,	Luminous by the explosion, and gave hissing purple sparks.
Porphyries and granites,	Hissing purple sparks, and luminous by the shock.
Pudding stones,	Similar hissing sparks. Oval pebbles more luminous than the sand.
Mochoas,	Good sparks from the arborescent parts, but only a hissing stream from the stone itself, which is slightly luminous by the shock.
Pumice stone,	Hissing streams in some, and good sparks in others, slightly luminous.
Different kinds of glass,	Neither give a spark, nor are luminous.

STRONTIAN GENUS.

Native carbonate of strontites,	Only a hissing purple stream, but very luminous by the explosion.

COMBUSTIBLES.

Roll brimstone,	Gives no spark, and is scarcely luminous by the shock.
Flowers of sulphur,	Are not phosphoric.
Phosphorus,	Inflames both by the spark and shock.
Charcoal,	Some kinds afford good sparks, and are phosphoric, and some not.
Cannel coal and Sunderland coal,	Give sparks beautifully variegated, in minute spangles, radiated upon their surface; but they are not phosphoric.
Hard and dry peat,	Gives a very good spark, but is scarcely luminous.
Hard and brittle bitumen from Derbyshire,	Gives no sparks, but the fluid spreads uniformly and silently over its whole surface, like the electric light in an exhausted receiver; it is luminous by the shock.
Elastic bitumen from Derbyshire,	Is also luminous by the shock.
Jet and asphaltum,	Give the same phenomena as bitumen, but are not luminous by the explosion.
Amber,	Gives no sparks, but is phosphorescent, particularly fat amber.
Plumbago,	Gives good sparks, and is not phosphoric.

As many bodies possess the property of becoming phosphorescent by heat, the phosphorescence produced in the preceding experiments may in general be ascribed to the heat which accompanies an electrical discharge. But although the heat thus produced may be either the sole or an auxiliary cause of the phosphorescence which is excited in bodies which are known to be phosphorescent by common heat, yet it is obvious from other experiments, that electricity exercises a specific influence upon that peculiar structure or condition of bodies which causes them to give out light when heated.

Experiments of Dessaignes.

M. Dessaignes seems to have been the first person who established a relation between electricity and phosphorescence. He found that the metallic powders, such as those of zinc and antimony, which are the most phosphorescent, lose their luminous qualities in a damp state of the atmosphere. Even in dry weather antimony loses its power of phosphorescing if it be rubbed in a metallic mortar; whereas, in an insulated mortar the light is very much increased. Glass pounded in dry weather becomes much more luminous than when it is pounded in a damp state of the air. It loses this property entirely in wet linen; but being as it were self-insulated, it is not deprived of its phosphorescence, like antimony, by being pounded in a mortar, which is a conductor of electricity. In order to make adularia phosphoresce briskly, it must be pounded in an insulating or insulated mortar; and the handle of the pestle should likewise be insulated. M. Dessaignes also found that *if glass be calcined till its phosphorescence is diminished, it resumes that property by being exposed on an insulated support and subjected to a few electrical discharges, or to a current of electrical matter.* Other substances which have *lost their phosphorescence* by calcination resume it when electrified; but our author remarked *that electricity does not restore the phosphorescence of those substances which have been deprived of it by the light of the sun.*

In pursuing this branch of the subject M. Dessaignes found that those phosphorescent substances which are imperfect conductors of electricity, are susceptible of receiving the luminous property from the action of the sun's rays; that *non-conductors* will not thus phosphoresce at all, or at least very imperfectly; and that most conductors give out no light whatever. Orpiment, and some of the oxides of arsenic, tin, zinc, and lead, are exceptions to this remark, and also the muriate of tin and the sulphate and phosphate of lead. Non-conductors, and conductors which refuse to phosphoresce after feeble electrical discharges, become luminous after strong ones; while imperfect conductors that phosphoresce after weak electrical discharges give no light whatever when the discharges are much increased. In support of the analogy between electricity and phosphorescence, M. Dessaignes remarks that phosphorescence is affected by the presence of points. Fluor spar, which has the asperities produced by fracture, phosphoresces readily, while the entire and smooth crystal remains dark. The same is true of calcareous spar, adularia, apatite, emerald, and common salt. If both sides of the glass be rough, it phosphoresces throughout; but if one side be rough and the other polished, it only shines when the rough surface receives the heat. It is a fact still more curious, that when Iceland crystal with smooth faces is exposed to the solar rays, it acquires very little phosphorescence; whereas, if but one of the faces is roughened and exposed to the sun, it readily becomes luminous. In like manner, Arragonite becomes luminous when a fractured face is exposed to the sun, but acquires very little light when the smooth natural surface is exposed to it. M. Dessaignes likewise maintains that nearly all the bodies that are susceptible of phosphorescence by friction become luminous by heat, by electricity, and by exposure to light. The general view which our author takes of these phenomena is, that phosphorescence is produced by a particular fluid, which is set in motion by light, by heat, by electricity, and by friction, and that it is dissipated by overheating or too long exposure to light.

Experiments of Mr Pearsall.

The influence of electricity upon phosphorescence and the colours of certain bodies has been recently examined by Mr Pearsall of the Royal Institution, who has amply confirmed the general result deduced experimentally by M. Dessaignes, that bodies which have lost their phosphorescent property by calcination acquire it again when an electrical discharge is passed through them. Having submitted a piece of chlorophane to a powerful heat, it gave out a strong phosphorescent light of a *pale violet colour*; but the specimen decrepitated so much during its calcination that a piece of sufficient size to be electrified could not be preserved. He therefore placed the calcined fragments in a glass tube, and sent through them three electrical discharges, the effect of which was the emission of a *deep violet light*. He then heated the fragments upon platinum, and they emitted a phosphoric light of different colours. Some of the fragments appeared *green*, others *yellow*, and all of them finished by emitting a *deep violet light*. These colours were evidently distinct from those of the natural mineral, for a portion of the latter heated at the same time produced only a *feeble violet colour*. Another portion of the same specimen, calcined but not electrified, emitted no light when heated.

A specimen of chlorophane, whose phosphorescence had been destroyed by an intense heat, was exposed to the solar rays for two days without any of its phosphorescent quality being restored. A single electrical discharge, however, restored its phosphorescence, which increased in the ratio of the number and the intensity of the shocks it received. The green light emitted by the action of heat was more deep and of longer continuance after three, six, or even twelve discharges, than after one. Mr Pearsall obtained the same results with apatite and some diamonds; but electricity produced no effect in developing phosphorescence by heat in amethyst, sapphire, ruby, garnets, and other mineral substances which he tried. The following table contains the principal results obtained by our author.

Names of Minerals.	Natural Colours.	Effects of Heat.	Kind of Calcination.	Mode of electrifying them.	Effeets of Heat after being electrified.
Fluor spar.	White crystallized mass.	No light.	Decrepitating strongly.	Small fragments in a tube.	Feeble light.
Ibid.	Ibid. another specimen.	Ibid.	Ibid.	Ibid.	Momentary but distinct light.
Ibid.	Ibid.	Ibid.	Ibid.	Ibid.	Feeble light.
Ibid.	White crystals.	Feeble violet light.	Ibid.	A fragment.	Feeble *violet* light, ending in deep purple.
Ibid.	Green crystals.	Pale violet light.	Ibid.	Ibid.	*Yellowish green*, ending in intense brilliant *purple*.
Ibid.	Ibid. another specimen.	Violet light.	Ibid.	Six discharges through a tube.	*Green*, *violet*, and then *purple*.
Ibid.	Amber coloured crystals.	Strong violet and rose coloured light.	Ibid.	Ibid.	Bright *orange*, but of short duration.
Ibid.	Crystallized violet mass, the least coloured parts used.	Ibid.	Ibid.	Ibid.	*Yellow* or *flame* coloured light.
Ibid.	The most coloured parts of the same specimen.	Ibid. stronger.	Ibid.	Ibid.	*Yellowish green* light.
Ibid.	Another specimen, deep violet throughout.	Ibid.	Ibid.	Ibid.	Very fine bright *yellow* light.
Calcareous spar.	Crystals.	No light.	Heated to redness.	Solid piece, six discharges.	No light.
				Fragments in a tube.	Feeble and *reddish* light.
Ibid.	Ibid.	Ibid.	Ibid.	Small solid piece, six discharges.	Ibid.
Ibid. Dog-tooth spar.	Ibid.	Yellow light, steady and continuing long.	Ibid.	Solid crystal, six discharges.	*Orange* light, but only at a high temperature.
Diamond.		No light.	Ibid.	Single pieces, 12 discharges.	Pale blue light.
Apatite.	Fragment.	Luminous.	Calcined.	Single piece.	Yellow light.

In the course of these interesting experiments Mr Pearsall observed the curious fact, that the specimens of fluor spar, though colourless in their natural state, received a bluish tint when electrified, and the acquired phosphorescence was proportional to the depth of the tint. When a number of fragments were used, the larger fragments were of a blue colour, and emitted a blue light when heated, whereas the smaller fragments emitted only a pale yellow light. Mr Pearsall thinks it probable that the phosphorescent property is communicated by electricity only to the surface, which he considers as explaining the fact that fragments of different dimensions emit differently coloured lights.

In resuming the investigation of this subject, Mr Pearsall found, that bodies not naturally phosphorescent, such as statuary marble in its natural or calcined state, ivory when its carbonaceous part was removed, calcined mother of pearl, calcined oyster shells, calcined petuncles, egg shells, and lime, were not only rendered phosphorescent by heat after being strongly electrified, but acquired this property with a beauty, a variety, and an intensity of colour superior to those which occur in specimens that possess a natural phosphorescence. We regret that our limits will not permit us to give in detail a second series of experiments which Mr Pearsall performed with twelve different varieties of fluor spar, all of which gave distinct phosphorescence previous to their being electrified; but the general result of them may be thus expressed. When the natural spars emit by heat a light of different colours, the electric action produces only one of them; but when the mineral yields only one natural colour by heat, this is replaced, when electricity is applied, by a phosphorescence of various colours, among which the primitive tint does not appear. As the colours change with the number of electrical discharges, Mr Pearsall found the following to be the order of progression. The specimen was a green fluor.

1 discharge,	pale purple light when heated.
2	pale green, changing into purple.
3	the same colours, more intense and durable.
4	purple, with increased intensity.
6	green, brighter and deeper.
10	green bright; fine and more durable purple.
20	deep and more durable colours.
40	very rich colours, the purple at last inclining to red.
100	green colour, highly brilliant, and becoming yellowish. The purple had now a superb tint.
160	an intense light nearly white, followed with a brilliant green light, then with a durable purple, and then with a yellow accompanied with violet tints.

This specimen had been successively heated and electrified nearly fifteen times, and had suffered no deterioration in its phosphorescent property.

Mr Pearsall next shows that the property communicated by electricity was preserved even for *three* months, when the specimen was kept in the dark. Out of twelve fragments, two had completely lost their acquired phosphorescence by exposure to the sun for twenty-one days, five had nearly lost it, and six had experienced a modification in their colours by this exposure.

Mr Pearsall now examined the influence of electricity on the natural phosphorescence of bodies, and he found that an augmentation of intensity was produced, of which it is difficult to give an idea. Specimens of fluor whose pyro-phosphorescence was feeble or uncertain, were raised to the rank of highly phosphorescent bodies, and some of them even rivalled the Siberian fluor. At the end of fifty days some of these specimens still preserved the excess of phosphorescence which had been communicated to them, while others continued to exhibit the same order of colours.

Mr Pearsall has brought forward several experiments to prove that the phosphorescence of bodies, and the modifications it experiences, depend on their structure and mechanical condition. Phosphate of lime, for example, which in the form of *apatite* has an intense natural phosphorescence, has none when aggregated from a precipitation of it in a solution of muriatic acid, nor when obtained from powdered or calcined apatite. A calculus of phosphate of lime, however, gave green, yellow, and orange light when heated after having been calcined and exposed to twenty electrical discharges. Mr Pearsall also several times observed that the power of phosphorescence returned after it had disappeared.

With the view of showing that the phosphorescence was not owing to any radiating matter which was carried along with the sparks, Mr Pearsall inclosed coloured chlorophane in glass tubes hermetically sealed, and found them phosphorescent after 225 discharges. He found Voltaic electricity capable of producing phosphorescence in some cases and not in others; so that it differs greatly from common electricity in this property.

In explaining the preceding phenomena, Mr Pearsall considers the intense electricity of the Leyden jar as altering the structure upon which phosphorescence depends, by the vibratory motion which it communicates, and which allows the particles to take a new arrangement. When the body has had a new structure communicated to it by the vibrations or shocks of each electrical discharge, the action of heat is supposed by our author to permit the body to return to its primitive structure; and he conceives that the vibrations of the atoms during these changes of structure may produce light.

SECT. IV.—*On the Changes produced by Electricity on Odoriferous Bodies.*

Influenc on odori ferous b dies.

It has been recently discovered by M. Libri of Florence that electricity exercises a curious influence over odoriferous bodies. Having caused a continued current of electricity to traverse a piece of camphor, the odour of this substance became more and more feeble, and at last entirely disappeared. When the camphor has suffered this change, and is withdrawn from all electrical influence, and put in communication with the ground, it will remain without odour for some time, but it will afterwards resume its former properties slowly and gradually. M. Libri seems to have obtained a similar result with other odoriferous bodies; but he has not, so far as we know, given any more particular account of his researches.

SECT. V.—*On the Magnetic Effects of Electricity.*

Magne effects electric

During almost every period of the history of electricity, philosophers have pointed out strong resemblances between the phenomena which it exhibits and those of magnetism. Some of the most striking points of resemblance were, that each consisted, as it were, of two powers or directions of powers, of an opposite nature, and subjected to similar laws of attraction and repulsion; that the action of magnetism has a great analogy with that of electricity; that the distribution of the forces in an electrified body differs very little from that of the forces in a magnet; and that the pyro-electrical tourmaline has the strongest resemblance to an artificial magnet.

These views were powerfully confirmed by the fact, often enome- a and Laws.

observed, that magnetism was communicated to bodies by a stroke of lightning, and that the compass needles of ships have had their polarity changed by a similar cause. The ship Dover was struck by lightning in the Atlantic on the 9th January 1749; and in four compasses on board, one of which was in a brass box, and the other three in wooden boxes, *all the needles had lost their virtue.* At first their polarity seemed to have been nearly reversed, but after a little while they moved about in every direction, and were of no use. Mr Gowin Knight, having examined one of these compasses, observed that the outward case was joined together by pieces of iron wire, sixteen of which were found in the sides of the box and ten in the bottom. By applying a small needle to each of these wires, Mr Knight found that they were all strongly magnetical, particularly those which had joined the sides.

Another very remarkable case occurred on board the New York Packet, in its voyage from America to Liverpool in 1827; and as a very accurate description of it was communicated by the Rev. Mr Scoresby to the British Association at York in 1831, we shall lay before our readers his own abstract of it. "Soon after the commencement of the voyage, this vessel encountered a severe thunderstorm, and received a stroke of lightning, which shattered the masts in several parts, and started some of the exterior planks of the bends. This was in the morning before day-light. The weather continuing unsettled, and the air in a highly electric state, with water-spouts in various directions around, the captain, fearing another explosion from the highly charged atmosphere, put up a lightning conductor which he had on board. In the afternoon of the same day the ship was a second time struck, but preserved by the conductor, though the iron of which it was composed was destroyed, and fell in melted globules upon the deck. No lives were lost, though some of the crew received heavy shocks; whilst one person, an invalid passenger, derived essential benefit from the electric discharge. Mr Scoresby had an opportunity of examining the vessel immediately on her arrival in Liverpool, when, on investigating the condition of the iron on board, he found almost every article capable of permanent magnetism, with sensible polarity. Table-knives and forks were capable of lifting needles or small nails, and one knife sustained a travelling-trunk key. Most of the watches on board suffered by the magnetic influence, especially those which were under the pillows of their owners in bed. These were all stopped, and on examination were found so highly magnetic that portions of the steel-work were capable of suspension by each other, in a chain of three or four pieces. Of one of these pieces (the cap-spring) Mr Scoresby made a pocket compass, which was exhibited when his communication to the association was made, and was observed to be in all respects a delicate and perfect instrument."

xperi- ents of ranklin.

In enumerating the points of analogy between lightning and electricity, Dr Franklin remarks that they have both the power, not merely of reversing the poles of magnets, but of completely destroying their magnetism. By discharging four large jars through a common sewing needle, he communicated to it such a degree of magnetism, that it placed itself on the plane of the magnetic meridian when it was made to float on water. If at the time of receiving the discharge the needle lay east and west, the end at which the discharge entered pointed north; but if the needle lay north and south, the end which lay to the north continued to point to the north, at whatever end the discharge entered. He found also that the magnetic intensity developed in a needle was a *maximum* when the needle lay north and south, and a *minimum* when it lay east and west, at the time of receiving the electrical discharge. If the charge of a large jar or battery is transmitted through a steel wire perpendicular to the horizon, it will be permanently magnetised, and the lower end, at the time of the discharge, will afterwards turn to the north when it is made to traverse in a horizontal plane. If we now replace the wire in its vertical position, the end which was formerly the lowest being now the highest, and again transmit the discharge, the polarity of the needle will either be completely destroyed, or the poles will be reversed.

Phenomena and Laws.

It has been found also that the polarity of a natural magnet may be completely destroyed by transmitting through it the charge of a battery.

Experiments of Beccaria.

In repeating the experiments of Franklin, Beccaria discovered that lightning always communicates the magnetic polarity to bodies containing iron, and he observed this phenomenon even in common bricks that had been struck by lightning. Guided by the observations which he made on the polarity of such bodies, he was able to trace the directions which the lightning had taken in passing through them.

Of Van Marum.

A series of elaborate experiments were made by Van Marum, on the magnetic effects of electricity. He employed a battery of 135 jars, containing 130 square-feet of coated surface, and he transmitted the powerful charges which it yielded through watch-spring needles from three to six inches long, and also through steel bars nine inches long, between a quarter and half an inch broad, and nearly a line thick.

In this way he found that when the needle or bar was placed horizontally in the plane of the magnetic meridian, its north end acquired north polarity, and its south end south polarity, in whatever direction it received the discharge. When the bars possessed some degree of polarity before receiving the shock, it was either diminished or reversed after receiving it. When the needle or bar received the shock in a vertical position, its lower end became the north pole whether it had been previously magnetic or not. Generally speaking, the degree of magnetism which was communicated was as strong in a horizontal as in a vertical position. When the needle was placed in the magnetic equator, and received the discharge longitudinally or along its axis, it received no magnetism whatever; but when *the shock was passed through its width, or at right angles to its axis*, the needle received a considerable degree of magnetism, the end which pointed to the west becoming the north pole, and that which pointed to the east the south pole.

When the charge was so powerful as to render the needle hot, no sensible polarity was communicated to it.

Discovery of electro-magnetism by Professor Oersted.

Such was the state of our knowledge respecting the connection between electricity and magnetism, when Professor Oersted of Copenhagen, led by theoretical views, established a most interesting relation between these two powers, and laid the foundation of the new science of *Electro-magnetism*, or *Magneto-electricity*. The fundamental fact which Mr Oersted discovered may be thus expressed.

When a wire conducting electricity is placed parallel to a magnetic needle properly suspended, the needle will deviate from its original or natural direction. This deviation follows a regular law.

1. If the needle is *above* the conducting wire, and the positive electricity goes from right to left, the *north* end of the needle will be moved *from* the observer.

2. If the needle is *below* the wire, and the positive electricity passes as before, the *north* end of the needle will be moved *towards* the observer.

3. If the needle is in the same horizontal plane with the wire, and is between the observer and the wire, the *north* end of it will be *elevated*.

4. If the needle is similarly placed on the opposite side,

Phenomena and Laws.

the *north* end of it will be depressed. In these two experiments the needle must be very near the wire.

From these simple facts Mr Oersted concludes, *that the magnetical action of the electrical current has a circular motion round the wire which conducts it.* This law will be understood by inspecting Plate CCXIII. fig. 10, where, if AB is the conducting wire or the direction of the positive electricity, the circle *c d e f* will be the plane in which the magnetical circulation takes place. The small arrows show the direction of the austral or polar magnetism, the sharp ends or heads of the arrows indicating the direction in which the *austral* magnetism, and consequently the *north end* of the needle, is *repelled*, and the *boreal* or northpolar magnetism is attracted; while the opposite ends of the arrows indicate the direction in which the *boreal* magnetism, and consequently the *south end* of the needle, is *repelled*, and the opposite magnetism attracted.

Plate CCXIII. Fig. 10.

Dr Colladon's experiments with ordinary electricity.

The preceding discovery was made with the electricity of the galvanic battery, but it is equally true when a strong current is obtained from the common electrical machine. An electric spark sent along a conducting wire passes too quickly to move the needle, and a current produced by the electrical machine does not appear to contain a sufficient quantity of electricity to act upon the needle, or rather to show its action. If the electrical effect of the current, however, is multiplied, its action upon the needle becomes apparent. In order to do this we must use, as Dr Colladon first did with success, Schweigger's multiplier, which is shown in fig. 11, where ABCDE is the wire which conducts the electrical current, bent several times, and covered with three folds of silk for the purpose of insulation. The needle NS is then inclosed within the coils of the wire, and the effect of the current upon it is obviously quadrupled by the *four* coils of the wire which surround it. The coils should be as near to each other as possible; and as they can be repeated a great number of times, the multiplication of the effect is almost unlimited. The needle is suspended by a single fibre of silk, and the sensibility of the instrument may be increased by using a magnet for the purpose of diminishing the directive power of the needle. When Dr Colladon brought the two ends of the wire of this apparatus to the two conductors of an electrical battery of 4000 square inches, so as to make the discharge go a little way through the air before it entered the wire, a current of sufficient strength and of some duration was obtained, which produced a considerable deviation in the needle. Dr Colladon also obtained a deviation of several degrees with this multiplier, by means of the electrical current obtained from an electrical machine.

Fig. 11.

Experiments of Dr Faraday.

These interesting experiments of M. Colladon have been amply confirmed and beautifully extended by Dr Faraday. Although MM. Arago, Ampere, and Savary had witnessed a successful repetition of M. Colladon's experiments, yet the conclusions to which they led were doubted by some and denied by others. Dr Faraday was therefore induced to repeat them with great care. He employed for this purpose the electrical machine, battery, and discharging train already described (see page 631).

The galvanometer which he used was sometimes a single one, consisting of sixteen or eighteen convolutions of copper wire covered with silk, and sometimes a double one, consisting of two independent coils, each containing sixteen feet of silked copper wire. The glass jar which covered the galvanometer and supported the needle was coated inside and outside with tinfoil, the upper part (left uncoated for the purpose of examining the motions of the needle) was covered with a frame of wire-work with numerous sharp projecting points. When this frame and the two coatings were connected with the discharging train, an insulated point or ball, connected with the machine in its most active state, could be brought within an inch of any part of the galvanometer, without the inclosed needle being affected by any ordinary electrical attraction or repulsion.

Dr Faraday expected, by means of the retarding power of bad conductors, to obtain from ordinary electricity the powers of Voltaic electricity. After the connections were properly made, a battery charged positively by about forty turns of the machine was discharged through the galvanometer, when the needle immediately moved. By repeating this experiment when the needle was vibrating, its vibrations were extended to above forty degrees on each side of the line of rest: on reversing the galvanometer the needle was equally well deflected in the opposite direction, the deflections being in the same direction as if a Voltaic current had passed through the galvanometer, the positive surface of the battery coinciding with the positive end of the Voltaic apparatus. Similar effects were obtained by taking the electrical current directly from the prime conductor, and dispensing with the battery altogether. When the electricity, too, was passed through an exhausted receiver to imitate the aurora borealis, and then through the galvanometer to the earth, it was equally efficacious in deflecting the needle.

From these and other experiments, Dr Faraday concludes that a current of common electricity, whether transmitted through rarefied air, water, brine, acids, and other imperfect conductors, or through wire, or by means of points in common air, is still able to deflect the needle (the only thing necessary being to allow time for its action), and is just as magnetic as a Voltaic current.

As it is by the galvanic battery, however, that this subject has been studied, we cannot pursue it any farther at present, and must refer our readers to the articles already mentioned, in which a full view of this new science will be given.

Sect. VI.—*On the Effects of Electricity upon Animal Bodies.*

Influenc of electri city on a mal bodi

The influence of electricity on the human frame, whether it is administered in small quantities so as to excite and surprise us, or in the more powerful and awful form of a stroke of lightning, must be well known to the least informed of our readers.

When any part of the body receives an electric shock, a disagreeable sensation is felt in the place; and, according to Dr Robison, it is sharper when taken from a long wire than from a large body. When the human frame forms part of the electric circuit, or when the charge of a Leyden phial is made to enter the body at one hand and pass out of it at the other, a violent concussion or shock is felt along the line of its passage across the breast and through the arms. This electrical shock, and the involuntary motion which accompanies it, arises no doubt from the obstructions which an imperfect conductor like the human body, composed of fluids and solids of different conducting powers, presents to the free passage of the electric fluid. If the charge is increased, the patient through whom it passes falls down under its influence, and suffers a temporary suspension of vital action; and if it is increased to a still greater degree, it will produce instantaneous death. This case is frequently exemplified when persons are killed by lightning; and a very remarkable instance of the laceration of the human body lately occurred, which could have arisen only from an obstruction to the free passage of the fluid. The case to which we refer presents us with a most singular variety of action exhibited by the lightning in passing through animal bodies; and it is so interesting, and so well described by Mr B. Boddington, the father of the gentleman who was struck with the lightning, that we shall present our readers with an abstract of it.

gular ects of htning.

On the 13th of April 1832, Mr and Mrs T. F. Boddington left Tenbury, occupying the hind barouche seat of their post-chariot, the servants being in the inside. About half past three o'clock, with the sun shining, and a serene sky, they observed a dark cloud to arise in the direction of their route. Soon after a clap of distant thunder was heard, but no lightning was seen. A few drops of rain having begun to fall, Mr Boddington put up an umbrella, and, after giving it to his wife, he put up another, and when he was in the act of extending the latter, a flash of lightning struck them both senseless, threw the horses on the ground, and cast the post-boy to a distance. One of the servants, after recovering from his alarm, looked out of the window, and saw the head of Mr Boddington hanging over the seat, and apparently lifeless. Jumping from the carriage, he raised his master's head, and found his clothes on fire, while Mrs Boddington was standing up tearing off her bonnet and shawls. She had neither seen the flash nor heard the thunder, but felt a sense of suffocation, and was putting off her things to obtain air. She and the servant then proceeded to extinguish the fire, which was still consuming her husband's dress. The lightning, passing down through the umbrella, penetrated through the bonnet into Mrs Boddington's neck, and zigzagged along the skin of her neck to the steel busk of her stays, leaving a painful but not a deep wound, and affecting the hearing of the left ear. From the lower end of the busk the lightning pierced through all the garments down to her thighs, where it made wounds on both; but the one on the left was so deep and so near the femoral artery, that the astonishment is she escaped with her life, the hæmorrhage being very great. None of her clothes were burnt, notwithstanding their inflammable nature, nor did any of her wounds present the appearance of burns. Mr Boddington, after remaining insensible for ten minutes, revived, and felt a pain all over him. The main force of the shock passed down the handle of the umbrella to his left arm, though a portion of it made a hole through the brim of his hat, and burnt off all the hair that was below it, along with his eye-brows and eye-lashes. The fragments of the burnt parts falling into the eyes, deprived him nearly of sight for two or three days. The electric stream shattered his left hand, melted his gold shirt-buttons, and tore the clothes in a most extraordinary manner, forcing parts of them, with the buttons, to a distance, and inflicting a deep wound under their position on the wrist. The arm was laid bare to the elbow, a severe wound was made in his body, and every article of his dress torn away as if by gunpowder. It then passed to the iron of the seat, wounding his back, the whole of which was literally flayed. The horse rode by the postilion was killed. A very striking difference was observed in the wounds of Mr and Mrs Boddington. Hers were fractures of the flesh. His, on the contrary, whether deep or shallow, were all burns, and had a white and blistered appearance. No wound was visible on the dead horse excepting an indentation on the head where the fluid entered, discolouring the spine in its passage.

xperiments of an Marum on ls.

For the purpose of determining in what manner death is produced by a powerful electric discharge, Van Marum sent the electric shock through eels one and a half and three and a half feet long. The smaller eels were instantly killed when the shock was sent through their whole body; but when the charge was only sent through individual parts, these parts only lost their irritability, while the rest retained it. When the shock went through the upper and fore part of the head of the large eels, the under jaw, as well as the muscles of the neck and belly, and even the lower part of the body, preserved their irritability, while the parts which conveyed the charge had totally lost it. When smaller shocks were sent through warm-blooded animals, similar effects were observed; and hence it has been inferred that the circulation of the blood cannot take place when such an effect has been produced, and that the suspension or destruction of life must arise from this cause. When the shock does not affect the large arteries the animal may recover, provided that the spinal marrow and the cerebellum are not injured.

Experiments of Morgan.

Various experiments have been made by Mr Morgan and others, with the view of ascertaining the influence of electricity on the animal functions. Mr Morgan found that if the diaphragm forms part of the circuit between the inside and outside coating of a jar containing two square feet, the lungs will make a sudden effort, followed by a loud shout. When a small charge is similarly applied, a violent fit of laughter is always produced, even on the gravest persons. A strong charge transmitted through the diaphragm is frequently accompanied by tears and sighs, and sometimes by fainting. When a strong charge is sent through the spine of a person standing, he will frequently either drop on his knees, or fall prostrate on the floor. A strong charge having been transmitted accidentally through Mr Singer's head, he felt the sensation of a violent but universal blow, which was followed by transient indistinctness of vision and loss of memory, but no permanent injury was received. When the charge of a battery is sent through the head of a bird, its optic nerve is always injured or destroyed; and when a smarter shock is given to a larger animal, a tremor and depression, with a general prostration of strength, is produced.[1]

Mr Cavendish observed that the sensible shock depended more on the quantity than on the intensity of the charge, a double degree of intensity with only half the quantity invariably producing a less powerful shock. According to Volta, only a little more electricity is necessary to produce an equal shock from a larger surface. A surface, for example, sixteen times as large, required only an elevation of the electrometer to one tenth of the number of degrees. Dr Robison informs us that the shock obtained from a small charge given to a large surface, yields a less unpleasant shock than a large charge given to a small surface. As these observations, however, depend upon individual feeling, and as it is known that different persons are affected in very different ways with the same degree of electricity, they may not be generally correct.

Effects of electricity on the pulse.

The influence of electricity on the pulse has been examined by different authors, though with some variety of result. M. Trembley found that the arterial pulse was quickened in persons electrified. M. Boze was of the same opinion; but the Abbé Nollet could not discover any increase in the rapidity of the circulation of various animals which he electrified. Cavallo, on the contrary, informs us that an experienced medical electrician assured him that, "in a diseased state of the body, an obvious acceleration of the pulse was observed to result from the application of electricity."

Experiments of Nollet.

In the experiments made by M. Nollet, his attention was directed to other points beside the state of the pulse.

---

[1] Dr Young observes, that a minute tremor communicated to the most elastic parts of the human body, particularly to the chest, occasions a nervous agitation, not unlike the effect of weak electricity.

His experiments were made with birds, cats, and the human subject; and having selected and carefully weighed pairs of the animals, he communicated to them a current of electricity for some hours, when they were again weighed. The loss sustained was ascribed to perspiration. The general result was, that the animal which was electrified was always found to be lighter than the one which was not. The persons who submitted to these experiments suffered no inconvenience from them. They experienced a slight degree of exhaustion, and an increase of appetite, but none of them found themselves sensibly warmer.

Experiments of Van Marum.

In order to settle these questions respecting the influence of electricity on the pulse and on insensible perspiration, Van Marum selected *eleven* persons, and repeated the experiment *four* times upon each, with negative as well as with positive electricity. They were placed in a room so remote from the machine that they could not hear the noise which was made in working it. They were placed on insulating stools, and their pulse was felt and carefully counted both when the machine was in motion and at rest. The general result was, no decided acceleration was observed, a few additional beats having taken place in some cases. In general, however, *there was a great irregularity in the pulse.*

The next experiment of Van Marum was a very interesting one. He placed a boy eight years old in one scale of a delicate balance, which scale was insulated by means of a silk cord. The boy being connected with the conductor, the balance was brought to a state of exact equilibrium. Having determined that the boy, previous to being electrified, lost 280 grains in an hour, he electrified him, and found that the loss was 295. In another experiment the boy lost 330 grains before, and 310 after being electrified. A girl seven and a half years old lost 180 grains before, and 165 after being electrified. A boy eight and a half years old lost 430 grains before, and 290 after being electrified. A boy nine years old lost 170 before, and 240 after being electrified. As this boy had remained very quiet during the experiment, the increase was ascribed to electricity, and the experiment was carefully repeated. He now lost 550 grains before, and 390, 330, 270, 550, and 420 after being electrified. Hence it appeared that the insensible perspiration had rather decreased than augmented.

Medical electricity.

The powerful influence of electricity on the human frame led the more sober part of the medical profession to view it as a valuable auxiliary in the healing art, while those who were more sanguine regarded it as an universal medicine, which might be resorted to in every form of disease. Charlatans of every degree found the electrical machine a lucrative article of trade; and there were not wanting well-meaning enthusiasts who contributed to prolong the reign of medical electricity.

But though electricity has not yet taken up a position in the healing art, there can be no doubt that in various disorders its application has been found advantageous, and that patients have, in a particular class of diseases, experienced instantaneous relief.

Electrical machine for medical purposes. Plate CCXVI. Fig. 16.

The machine used for medical purposes should have sufficient power to yield a continued current of strong sparks. The diameter of the plate in a plate machine should be about twenty inches, and that of a cylinder about ten or twelve inches. The only apparatus necessary is a jar fitted up with Lane's electrometer (see Plate CCXVI. fig. 16), and a pair of directors, each consisting of a glass handle surmounted by a brass cap, with a wire a few inches long, carrying a ball at its extremity. A wooden point is sometimes substituted for this ball. When it is required to pass a shock through any part of the body, the directors are applied at the opposite extremities of the part, one director being connected by a wire with the inside coating, and the other with the outside coating of the jar, or, what is the same thing, with the receiving ball of Lane's electrometer, previously placed at such a distance from the ball of the jar as to yield a charge of the proper magnitude. When sparks are to be administered, it is done with the director and brass ball; but when the organ is very delicate, such as the eye, a stream of electricity is thrown upon it from the wooden point, held at the distance of about half an inch. An insulating stool, capable of holding a chair for the patient, is also necessary. In certain cases a brass plate, communicating with the inside of the jar, is placed in the bottom of the chair, so as to apply itself to the lower part of the body, when the electricity is required to pass through the abdomen or adjacent parts.

In his *Introduction to Electricity and Galvanism*, Mr Carpue has enumerated several diseases in which it seems to be almost certain that electricity will be beneficial. The following is an abridgment of his list:

1. *Contractions.*—In those which are of long duration immediate relief has been obtained, provided they depend on the affection of a nerve.

2. *Rigidity.*—Cases of this kind have been frequently relieved after some perseverance.

3. *Sprains, Relaxation.*—Electricity applied after the subsidence of the inflammation is generally advantageous.

4. *Indolent Tumours.*—Strong sparks and slight shocks are frequently very effectual. Schirrous indurations of the breast have been often successfully dispersed. Ganglions have also been removed from the wrists or feet.

5. *Chilblains.*—Electricity is a good preventive, and in two cases they were removed by electric sparks.

6. *Deafness.*—Sparks thrown upon the mastoid process, and round the *meatus auditorius externus*, and drawn from the same part on the opposite side, generally afford relief, and about one in five have been permanently cured.

7. *Opacity of the Cornea.*—A current of electricity thrown for about ten minutes a day on the eye from a wooden point, sometimes cures this disorder. It is said to yield most readily when originating from the small-pox. In one case the disorder always returned when the electricity was discontinued.

8. *Gutta Serena.*—The method of electrifying the eye for the opacity of the cornea has been occasionally successful in this disorder.

9. *Knee Cases.*—Pains and swellings in the knee have been removed to the extent of one case in ten by sparks.

10. *Chronic Rheumatism.*—Sparks given for ten or fifteen minutes every day have afforded numerous cures. A few days is sometimes sufficient; but in cases of long standing considerable perseverance is necessary.

11. *Acute Rheumatism.*—An electrified current of air applied about a month, effected a cure in one case out of six.

12. *Palsy.*—Moderate shocks, with sparks occasionally, have been successful in about one case in every fourteen.

13. *St Vitus's Dance.*—This has also been frequently relieved by electricity.

A work in two volumes has been written by the Abbé Bertholon, a very respectable and scientific individual, in which electricity is regarded as a power which exercises an extensive influence in the cure of disease; and there is scarcely any class of disorders in which this credulous author has not represented it as having been successful. He considers the electricity of the atmosphere as a principal cause of the number of deaths, particularly sudden deaths, and as having a marked influence on generation, conception, and parturition.

Although several works of rather an empirical character have been more recently written on medical electricity, yet no philosopher of any eminence, with the exception of Professor Marianini, has devoted any attention to the subject. This ingenious author has published more than one memoir entitled "*On some Cases of Palsy treated by means of Electricity produced by a Voltaic Apparatus.*"[1] He has given a minute account of the cases in which electricity proved efficacious, of those which were attended with some amelioration, and of those in which it was wholly unsuccessful. He gives excellent general directions for the application of electricity, and mentions some curious facts which have occurred in his practice. Our author recommends electricity in the strongest manner as a moral remedy in palsy, and advises philosophers to study, more attentively than they have done, the influence of this powerful agent upon the human frame. As M. Marianini did not use ordinary electricity, we cannot with propriety give any further account of his labours here. We shall only remark, that it will be a most interesting study to compare the effects produced with the intense electricity of the machine, with those produced with the more copious quantity yielded in the Voltaic apparatus.

SECT. VII.—*On the Effects of Electricity upon Vegetable Bodies.*

fects of ectricity vege- bles.

It has been distinctly shown by Priestley, Ingenhousz, and Sennebier, but especially by Theodore de Saussure, that the various parts of plants act upon atmospheric air; that they insensibly disengage a large quantity of carbonic acid at the expense of the oxygen; and that, owing to some combination within the plant, they sometimes exhale pure oxygen. Now, as all carbonic acid has vitreous electricity, this exhalation of the acid from plants ought to furnish an abundant supply of it to the atmosphere. M. Pouillet, of whose researches we have already given an abstract, has placed this truth beyond a doubt.

From this fact alone we might reasonably infer that electricity performs an important function in the phenomena of vegetation; but so little attention has been paid to this subject, that we have some hesitation in laying before our readers the very imperfect and unsatisfactory experiments which have been recorded. The best experiments, indeed, have entirely a negative character; and the general result of them is given when we say that electricity appears to have no decided efficacy as a stimulus to vegetable life.

The recent discoveries, however, which have been made on endosmose and exosmose by M. Dutrochet, render it extremely probable that an electrical action is the cause of the ascent of the sap in plants; but as M. Poisson continues to ascribe these curious facts to capillary action, and other philosophers to other causes, we must wait for further experiments before we can treat this subject as a branch of electricity.

PART II.

DESCRIPTION OF ELECTRICAL APPARATUS.

ectrical paratus.

In the preceding part of this treatise we have already had occasion to refer to several pieces of electrical apparatus, and particularly to two or three varieties of the best machines for generating electricity by friction. Notwithstanding this slight anticipation, however, we must resume the subject at some length, on account of its great importance in a popular and practical view of the science.

The various kinds of electrical apparatus may be classed under the four following heads:—

1. Instruments for generating and collecting electricity.
2. Instruments for accumulating electricity.
3. Instruments for indicating the presence of electricity, and measuring its quantity.
4. Instruments for miscellaneous purposes.

CHAP. I.—DESCRIPTION OF INSTRUMENTS FOR GENERATING AND COLLECTING ELECTRICITY.

Instruments for generating electricity.

The instruments which belong to this chapter are, electrical machines, atmospherical conductors, and electrophori.

SECT. I.—*Description of Electrical Machines.*

The simplest of all pieces of apparatus for generating electricity is a tube or rod of glass, which, when rubbed with a piece of woollen cloth, will yield as much electricity as will charge a jar in a short time. In consequence, however, of the labour which attends this operation, it has been usual to turn a sphere or cylinder of glass round an axis by a simple winch, or by a double wheel and band, for the purpose of generating electricity rapidly, and without fatigue to the operator.

We have already exhibited two of these machines in Plate CCIX. fig. 3 and 6, and described their general construction. It is easy to modify this construction in various ways;—and for particular purposes and particular classes of experiments particular forms of the machine may be most convenient: But as the philosopher is best capable of introducing such modifications for his own use, we shall not occupy our pages with the descriptions of electrical machines which have sprung more from the fancy and caprice of individuals than from the wants of the science.

There can be no doubt that the plate-glass machine is the most commodious and the most powerful form of the electrical machine.

We have already described, and given representations of very excellent plate-glass machines in Plate CCIX. fig. 1, 2, and 7, and in Plate CCX. fig. 1–5, of the last of which we shall give a fuller description; but we have reserved to the present chapter the description of the best form of the electrical machine with which we are acquainted, and which we owe to the ingenuity of Mr Snow Harris, F. R. S. Plymouth.

1. *Description of Mr Snow Harris's Electrical Machine.*

Mr Snow Harris's electrical machine. Plate CCXIV. Fig. 7.

This machine, which is shown in perspective in Plate CCXIV. fig. 7, consists of a circular disc of plate glass Z Z, three feet in diameter, mounted on a horizontal axis, resting on two horizontal supporters of mahogany. These supporters are themselves sustained by four vertical mahogany columns, fixed upon a firm frame as a base. To the lower side of this frame are fixed four legs M, N, O, P, upon which the whole machine rests; and these legs again rest upon another steady frame R, S, T, furnished with rollers, so as to move it easily into any required position, and likewise with three levelling screws R, S, T, for placing it horizontally. By these means the machine may be so adjusted and fixed that the axis of the plate of glass, which has a free motion backwards and forwards in the holes in which it turns, may not tend more to one side than to the other, and occasion an equal action on the rubbers. The rubbers, which are four in number, are insulated on pillars of glass A, B, one placed at each extremity of the horizontal diameter A, B of the plate. The positive conductor C, B, D projects in a vertical position in front of the plate Z Z, while the negative conductor passes in a curvilineal direction behind, and connects the rubbers of each side.

---

[1] *Ann. dell. Scienz. del Regno Lombardo-Veneto*, Marz. et Avr. 1833.

The plate of glass is turned by an insulated handle, immediately in front of which is placed a short index, which is fixed to the axis, and which moves over a graduated circle L, attached to the horizontal part of the frame, and through the centre of which the axis passes. In this manner the number of revolutions of the plate may be accurately registered.

In order to strengthen the centre of the plate, two smaller plates are cemented to each side by varnish; and a small stop is inserted into the axis, to prevent the pressure from increasing beyond a certain point.

When the machine is used for ordinary purposes, the conductors shown in fig. 7 are employed; but when it is employed to accumulate electricity, the conductors should have the smallest extent possible, and, excepting at the receiving points, where they collect the electricity from the edge of the silk flaps about H, H, they should be covered with sealing-wax. In this case the positive conductor is formed of small straight tubes, as shown in fig. 8, and its extremities terminate in balls of varnished wood, through the substance of which the metallic communications pass.

Fig. 8.

2. *Description of Van Marum's Electrifying Machine.*

Van Marum's electrical machine. Pl. CCX. Fig. 1-5.

This machine, to which we have made a brief reference in Sect. III. Chap. II. Part I., is represented in elevation and in section in fig. 1 and 2 of Plate CCX. The plate of glass AB, which is thirty-one inches in diameter, is sustained by a single pillar E, at the upper extremity of which are two similar brass collars I, I, one of which is shown separately in fig. 4. The horizontal axis MN rests upon these collars, and this axis carries a counterweight L, in order to balance the plate of glass and its appendages, and thus equalize the friction on the collars. The rubbers, which cannot be seen in the section, fig. 2, are shown at *m*, *n*, fig. 1. The pair at *m* is attached to the ball O, and supported by the glass pillar *e;* and in like manner the pair at *n* is attached to the ball P, and supported by the glass pillar *f.* A horizontal section of the rubbers and balls is shown separately in fig. 3. A semicircle of brass CD is attached to an axis *g* that turns on the ball G, resting on the pillar F, so as to give the conductor CGD a motion round that axis. Collectors six inches long and two and a half in diameter are placed at C and D, to collect the electricity from the revolving plate AB. At the outer end of the axis *g* is a copper tube H*h*, terminating at its lower end in a ball H, and its upper end in a smaller ball *h*, two inches in diameter, which, screwing into G, will fix the tube H*h* in any position round *g*. An arch of brass wire *cld*, half an inch in diameter, is fixed to the end of the bearing piece K, and moves round I into any given azimuth, so as to be placed, as in fig. 1, opposite the rubbers *m*, *n*, or at right angles to them. In like manner, the conductor CGD can be placed either horizontally, so that the collectors C and D may be opposite the rubbers *m* and *n*, or vertically, as shown in fig. 1. By this apparatus it is easy to produce either positive or negative electricity. In the position of the conductor shown in fig. 1, where CGD is at right angles to the rubbers, and where the rubbers are connected with the ground by the arch *cld*, and by the wire KK, fig. 2, the conductor G will give *positive* electricity; but when we wish *negative* electricity, the conductor CGD is placed horizontally, with its collectors C, D opposite the rubbers, and the arch *cld* is placed vertically, so as to insulate the rubbers.

A mahogany cap T covers the metallic caps of the supports, in order to insulate them more perfectly. A hollow ring of mahogany, VX, is, for the same reason, made to cover the metallic socket into which the support is inserted. In fig. 3, *a*, *b*, *a*, *b*, are four pieces of gum-lac. In fig. 1 and 2, W is the handle by which the machine is wrought.

3. *Description of Hare's Electrical Machine.*

Hare's electric machin Pl. CCI Fig. 7.

This machine, which we have previously noticed, differs from those generally made, in having its glass plate horizontal; and it is considered by its inventor, Professor Hare of Philadelphia, as giving negative electricity in a way preferable to that in which it is obtained in Van Marum's machine. The glass plate MN, thirty-four inches in diameter, is supported on an upright iron bar PR, about an inch in diameter, and covered by a stout glass cylinder, sixteen inches high and four and a half inches in diameter, open only at the base, through which the bar is introduced so as to form its axis. At the top of the bar PR is a block of wood turned to fit the cavity at the apex of the cylinder, and cemented therein. The external apex of the cylinder is fixed by cement into the brass cap which carries the plate. The glass cylinder, which is liable to no strain, effectually insulates the plate from the iron axis PR. The brass cap seen at P is surmounted by a screw and flange, which, with the aid of a corresponding nut and discs of cork, keeps the plate firm. The wheel W, driven by a handle, communicates by means of a band with another wheel about twenty inches in diameter, placed on the iron axis RS.

"Nearly the same mode of insulation and support," says Dr Hare, "which is used for the plate is used in the case of the conductors. They consist severally of arched tubes of brass (ABC, DEF), of about an inch and a quarter in diameter, which pass over the plate from one side of it to the other, so as to be at right angles to, and at a due distance from, each other. They are terminated by brass balls and caps, which last are cemented on glass cylinders of the same dimensions nearly as that which supports the plate. The glass cylinders are suspended upon wooden axes, surmounted by plugs of cork turned accurately to fit the space which they occupy. The cylinders are kept steady below by bosses of wood which surround them. In this way the conductors are effectually insulated, while the principal strain is borne by the wooden axes."

The collectors are shown at MN in connection with the *positive* conductor ABC, and the rubbers are shown between P and the balls D and F in connection with the *negative* conductor DEF. The advantage of this form of the machine over that of Van Marum is, that the two conductors are permanently fixed in their places, and that positive and negative electricity can be at any time obtained without any change in the machine. Dr Hare considers the band as of advantage in preventing the plate from being cracked by any hasty effort to put it in motion when it adheres to the cushions, as it often does. Dr Hare uses a winch on the other side of the wheel, so that two persons, or one with both hands, may drive it.

The great expense of large cylinders and plates of achines silk bs; glass, and their liability to injury, have induced artists to construct electrical machines of different substances. M. Walckiere de St Amand of Brussels constructed a machine of extraordinary power, which consisted of a web of varnished silk twenty-five feet long and five feet wide, revolving upon two wooden cylinders covered with woollen serge. During the revolutions of the cylinders, the silk moves between two cushions, each seven feet long and two inches in diameter, covered by cat's skin or hare's skin, and moveable so as to vary the friction. The machine was driven by four men, and it had so great power that it gave sparks fifteen inches long, and nobody durst take a spark from it but with the shoulder and elbow.

varnish- paste- ard; Dr Ingenhousz constructed machines with discs of pasteboard four feet in diameter, and soaked in copal or amber varnish dissolved in linseed oil. They were covered with the same varnish, and were mounted upon an axis or flat board, three inches broad, and covered with flannel or hare's skin, being placed between each two discs, so as to act as a rubber. Sparks one and even two feet long were given out by the front disc when the knuckle was presented to it.

wooden scs. Wooden discs, and cylinder discs of gum-lac partly immersed in mercury, which acted on the rubber, and stretched varnished ribbons, have been all used in the construction of electrifying machines, but it would be an unprofitable task to describe them.

4. *General Observations on the Construction and Use of the Electrical Machine.*

bserva- ons on e electri- l ma- ine. Although in fine dry weather, and in a warm and dry place, a good electrical machine may be brought into an excellent state of action, merely by wiping it with a warm linen cloth, and afterwards with a silk handkerchief, yet in a different state of the atmosphere, and in humid apartments, every precaution is necessary to insure the vigorous and steady action of the machine. By turning the machine before a fire, or placing it in a current of heated air, or, as Dr Faraday suggests, by placing it over a sand-bath or a hot iron plate, whose temperature does not exceed 212 degrees, the different parts of the machine will be thoroughly dried and heated without affecting the cements.

lethods heating e ma- ine. We have already described (see page 576) the improvement of Mr Ronalds, who heats the inside of the machine, &c. by a spirit-lamp. Dr Faraday recommends the heating of a cylinder-machine by placing a chemical Argand lamp with a low flame beneath the cylinder, and to support a plate of metal nearly six inches square, about an inch above the chimney of the lamp. This plate, by being heated, varies the air above it, and produces a large moderately heated current, which encircles the cylinder, and thoroughly warms it. Care must be taken not to heat the cylinder in spots, but to bring it, and especially the insulating parts, to an uniform temperature, which shall never be sufficient to melt the cement which is used in any part of it.

The state of the rubbers requires particular attention. They must be carefully freed from dust, and supplied with a soft and uniform coating of amalgam, which should always be rubbed in a mortar with tallow previous to being used. Large spots of amalgam should be removed from the cylinder or plate, either by the nail or a piece of wood. Dr Faraday remarks, that a few spots of amalgam rather increase than diminish the activity of the machine, and that the silk which proceeds from the rubber is better when impregnated with amalgam than when free from it. Dr Faraday adds, that it is often useful to hold a piece of silk, with some amalgam adhering to it, against the revolving plate or cylinder, and also to rub the surface of amalgam on the rubber with the same amalgamated silk. When the machine is thus put into good action, and the prime conductor removed, it should discharge a continued series of brushes from the edge of the silk, and abundance of sparks flying round the glass.

SECT. II.—*Description of the Electrophorus.*

Electro- phorus of Volta. Plate CCXIV. Fig. 9.

This ingenious instrument, which was invented by the celebrated Volta, is shown in Plate CCXIV. fig. 9. It consists of a circular metallic disc A, or a plate of wood covered with tinfoil, having an insulating handle of glass screwed into a nut E, made of wood or brass. The plate A is called the *upper conductor*, or *cover*. The next plate B, called the *resinous plate*, consists of a plate half an inch thick, composed of equal parts of shell-lac, common resin, and Venice turpentine, poured when hot upon a marble or stone table. The next plate is a metallic one C, called the *lower conductor*, or *sole*, which may be either separate or not from the *resinous plate* which rests upon it. The edge of the first plate A must be pretty thick, and made smooth and round. The following is the method of generating electricity with this apparatus.

The *cover* A being held in the left hand, rub the upper surface of the *resinous plate* B with a piece of dry fur, or whip it with a fox's tail or stripe of cat's skin. It will thus be excited *negatively*. Place the upper conductor above the resinous plate, and while it is there touch it with the finger, and then raise it by its glass handle. It will exhibit signs of positive electricity, and will yield a spark either to the knuckle or to the knob of a Leyden phial. If the cover A is again placed upon B, and, after being touched, again raised, it will give another spark, and *twenty* of these sparks will charge a Leyden jar of a moderate size. If the upper conductor A is not touched by the finger when placed upon B, it will exhibit, when raised, very faint, if any, traces of electricity. Now, as the resinous plate B continues, without any new excitation, to charge the upper conductor A, it is manifest that its electric condition is not destroyed by the contact and removal of A; and as it is necessary to connect the upper conductor with the ground, by touching it previous to its being raised, it is obvious that the electricity acquired by A is derived from its contact with B.

Fig. 10.

In order to explain the theory of the electrophorus, let us insulate the *lower conductor* C, by placing it on a glass stand, as in fig. 10, and let this conductor communicate with the pith balls of an electroscope. As soon as the upper surface of the cake B is excited, the pith balls will diverge with negative electricity. The negative electricity developed by the excitation of the upper surface has decomposed the natural electricity of C, by attracting the positive part and repelling the resinous part into the electroscope where it is indicated. If we now touch the conductor C, its negative electricity is carried off, and the positive undergoes no diminution; but, owing to the escape of the negative portion, the balls will collapse. If we now make the upper conductor A approach to B, and rest upon it, touching it at the same time with the finger, so as to connect it with the ground, the positive electricity of the cake B will decompose the natural electricity of A, repelling its negative electricity to the earth through the finger, and attracting its positive portion to its lower surface. This positive electricity of A attracting the negative electricity of the surface of B, and repelling the vitreous electricity of C, thus doubly tends to diminish the force by which this positive electricity is rendered latent or detained. Some of it, therefore, will be set free, and the pith balls will diverge with positive electricity, the divergence increasing as the conductor A comes nearer and nearer to the plate B. But as the positive electricity of the lower conductor has a tendency to repel the positive electricity with which we wish to charge the upper conductor A, we must cause the lower conductor C to communicate with the earth, as in fig. 9. By this means the electricity of C is reduced to its natural state, and the electricity of the upper surface of the cake B renders latent the maximum quantity of positive electricity on the upper conductor B.

Although the air produces a gradual dissipation of the electricities which are not rendered latent in an excited electrophorus, yet a well-constructed electrophorus will remain for months in full energy.

Lichtenberg's electrical figures.

M. Biot has ingeniously applied the principle of the electrophorus to explain what have been called the figures of Lichtenberg. If, when the electrophorus is charged, we raise the conductor A, and replace it on the cake B, by making it rest obliquely and upon its edge, then its positive electricity, accumulating itself wholly in the part which touches B, will become much stronger. It will escape from A, and will completely neutralize the negative electricity of the places towards which it goes, and after some contacts thus repeated upon different parts of the cake B, it will be all discharged. Hence we may deduce the following curious experiment: Instead of bringing back upon the negative electricity the positive which it has developed by its influence, carry it to another resinous cake B′, in its natural state. It will likewise attach itself to the surface of this cake, which will become positively electrified, and be capable in its turn of developing by its influence negative electricity. When the second cake B′ is thus charged, place upon its surface a disc of metal. We shall then have an electrophorus of an opposite kind to the first; and if this last is used to charge a third cake B″, the latter will have negative electricity; and in this way we may have any number of cakes, which will be electrified positively and negatively alternately. By this process we may electrify each surface only in certain parts, by attaching to the conductor A a rod and metallic button. If we then touch the resinous cake with this button, the electricity will be carried wholly to the point of contact. These points may be so chosen as to form the outlines of any regular or picturesque figures. In order to render these forms or pictures visible, we have only to strew on the surface of the resinous cake some light powder formed by a non-conducting substance, such as pounded resin or sulphur. The small particles of the resin, for example, will attach themselves only to the electrified spots; so that, by inverting the plate, all the rest will fall down by their own weight. These small particles affect regular and different arrangements, according to the nature of the electricity which makes them adhere; so that, by forming figures with the two electricities in different parts of the same plate, we obtain at the same time two sorts of figures.

Lichtenberg's method of making these figures visible is exceedingly beautiful. Having triturated sulphur and minium or red lead together in a mortar, so as to have a mixture of a yellow and red powder, he traced his figures on the resinous cake with the knob of a jar charged with vitreous electricity, and repeated them with the knob of a jar charged with resinous electricity. The compound powder being now projected, either with a powder puff or by means of a pair of bellows, upon the cake, the particles of sulphur which are electrified positively by trituration will attach themselves to the negatively electrified spots, while the negatively electrified particles of red lead will adhere to the positively electrified spots, so as to form a series of red and yellow figures when the cake has been inverted, and the rest of the powder has fallen from it. Many beautiful variations of this experiment have been devised; and Mr Bennet has shown how to make the figures permanent, by transferring them to paper.

When this experiment was first made, some German philosophers observed that the powder of rosin had sometimes a progressive motion which was not regular, and a new theory was the consequence of this. It was found, however, that they were very small insects of the genus *acarus* which happened to be in the powder, and which walked over the surface of the plate.

When well made and properly used, the electrophorus is a very powerful and useful instrument. Dr Klincock of Prague has shown, that if we transfer alternately the upper conductor from one resinous cake to another, and touch it after it is placed on the cakes, both cakes continually acquire more and more electricity, so that the upper conductor returns from either plate quite overcharged; and Leyden jars may be so strongly charged by them as to burst by the charge. The conductor returns from one plate charged with positive, and from the other charged with negative electricity.

M. Cavallo informs us that an electrophorus made of sealing-wax spread upon a thick plate of glass six inches in diameter was capable, when once excited, of charging a Leyden jar several times in succession, and so strongly as to perforate a card with the discharge. The upper conductor, when separated from the plate, was sometimes so strongly electrified that it darted strong flashes to the table upon which the electric plate was laid, and even into the air.

2. *Mr J. Phillips's Modification of the Electrophorus.*

Phillips electrophorus. Plate CCXIV Fig. 11.

As the contact of the operator's finger is of no other use than to connect the upper conductor with the earth, Mr John Phillips of York conceived the ingenious idea of producing the same effect by a momentary contact between the upper and under conductors. In effecting this he adopted three methods. The *first* consisted in raising a brass wire and ball from the lower conductor above the edge of the resinous cake, so that the edge of the upper conductor, or a brass ball upon it, may be brought in contact with it. This method answered very well with small instruments, in which the upper conductor can be easily directed to any particular point of the sole. In the *second* mode he fixed a narrow strip of tinfoil across the whole diameter of the resinous surface, so as to join the metallic sole or lower conductor. This construction answers perfectly, and is particularly suitable to large circles, whose upper conductors will infallibly touch some point of the metallic strip. The *third* method is to perforate the resinous disc quite through at the centre, and at any other point, and to insert in these perforations brass wires with their smoothest tops level with the resinous surface.

These three methods are represented in fig. 11, where *a* represents the ball in the *first* method, *b* the slip of tinfoil in the *second*, and *c*, *c*, *c* the conducting wires in the *third* and best method.

"On two of the largest electrophori," says Mr Phillips, "which I have made, both the second and third methods have been tried with equal success, but I much prefer the latter construction. The largest instrument has a cast-iron basis 20·5 inches diameter, resinous surface 19·75 inches, cover 16·25 inches. The resinous composition was made according to the directions in Mr Faraday's work on Chemical Manipulation. The cover is made of a plate of thin copper, strengthened at the edge by a thick brass wire, from which three radial brass wires pass to ectrical paratus.

the upper part of a central brass tube. In consequence of the angle they thus form with the plane of the plate, they act as pretty strong braces to maintain its figure, and the whole is very light. This central brass tube receives a cylindrical piece of wood, into which the insulating glass handle covered with sealing-wax is screwed by its wooden foot.

"With ordinary excitation this instrument will yield loud flashing sparks two inches long or more, and speedily charge considerable jars. The cover can be easily charged and discharged fifty or a hundred times in a minute, by merely setting it down and lifting it up as fast as the operator chooses, or the hand can work. In charging a jar or plate, I placed one knob of the connecting rod near the insulated surface of the jar or plate, and the other some inches above the cover; then the cover being alternately lifted up and set down, the jar is very quickly charged.

"One instrument nine inches in diameter, which I have made from the second plan above described, has very often surprised me by its remarkable power of retaining electrical excitation.

"The following example is worthy of notice. Early in September 1832 this instrument was removed from a house in York, where it had been for some time laid by, and brought to my present residence, distant one third of a mile. It was placed on a shelf on my book-cases, where it remained untouched until the 23d March 1833, and was then taken down *covered with dust.* It was found to be in a state of feeble excitement, so as to give sparks, visible in the day light, nearly one fourth of an inch long."

3. *Dr Faraday's Improvements on the Construction of the Electrophorus.*

nprovement on ne electrophorus.

As the electrophorus is an excellent substitute for an electrical machine in the laboratory of the chemist, from its being capable, when in good order, of inflaming the greater number of explosive mixtures operated upon in eudiometers, Dr Faraday has published his simple and ingenious methods of constructing this instrument.

He recommends the *cover* to be made of a piece of flat deal board one third or one half of an inch thick. This board is to be covered with pasted tinfoil laid on smoothly, particularly at the edges, and having all asperities rubbed down. The smoothest and flattest side being reserved for the lowest, a piece of glass tube seven or eight inches long is to be fixed on the centre of the other side for a handle; and towards the edge, on the same side, there should be fixed a piece of thick wire, about two inches long, bent outwards, and carrying a smooth metal ball at its upper end.

In order to make the resinous plate, a sheet of tinfoil one or one and a half inch wider than the cover is laid smoothly in the bottom of a flat dish, so that its edges may rise up all round, or in the inside of a hoop. Shelllac, common resin, and Venice turpentine, in equal proportions, are then to be melted together in a metallic vessel, and kept in a state of fusion from 230 to 240 degrees of Fahrenheit, till the vapour has ceased to evolve, and the fluid is quiet. When it has thickened by cooling, it must then be poured quickly, to avoid the formation of bubbles, upon the tinfoil, so as to form above it a cake one third or one half of an inch thick. The tinfoil should then be trimmed round its edge, and the cake should rest upon or be attached, by its tinfoiled side, to a board, to serve as a base and prevent it from injury. Dr Faraday observes that the *cover,* instead of a board, may be a plate of tin turned up round a thick wire, so that no sharp edge or angle may be presented outwards; and that for the resinous plate may be substituted a sheet of thin crown glass, having for its metallic base a sheet of tinfoil pasted to it. He adds also, that a large plate of mica without fissures, and coated in the same manner with tinfoil on one side, makes an excellent electrophorus. When glass, however, is employed, it must be well warmed at first, and kept warm during the experiments. The glass should be excited by being *rubbed* with a piece of silk with some amalgam spread upon it. It should be passed briskly over its surface backward and forward, and finally slid quickly off at its edge, so as not to rest upon any one point of the glass, lest it should discharge that portion of its surface.

Electrical Apparatus.

To return, however, to the use of the electrophorus first described. The resinous plate, when warm and dry, should be placed horizontally on its board, with the tinfoil below, and connected by a wire or chain with the ground, or with a discharging train when it can be obtained. See page 631. A piece of warm flannel, doubled up loosely into a roll about ten inches long, is to be held in the hand by one end; and the other end, being swung round in an inclined direction with a quick motion of the wrist, should strike the surface of the plate obliquely each time it passes, so as to produce an effect between that of a rub and a blow. When the whole surface of the warm resinous cake has been thus struck, it will be excited to a considerable degree. The *cover* of the electrophorus, being previously warmed, must now be lifted by its glass handle and placed on the middle of the resinous cake; and if the knob or metallic ball of the cover be now touched, a spark will pass from it to the finger. The cover is next to be lifted by its handle in a horizontal direction; and when it is two or three inches above the plate, the knob upon it is again to be touched by the finger or a ball, when a spark stronger than the first will be obtained. The cover being again put down on the plate, a third spark will pass between the knob and the knuckle. The cover being again lifted as formerly, a spark as strong as the second may be taken from it. By repeating this process, similar effects may be obtained for a long time. The sparks which are taken by the knuckle after putting the cover down are negative, and those which are taken after lifting it up are positive. Hence we charge a jar either positively or negatively, according as we take the spark when the cover is up or down. In order to obtain strong positive sparks, the cover, when on the resinous plate, must be touched with the finger, which must be removed before the cover is lifted up; and to obtain the strongest negative sparks, the cover when raised should have all its electricity carried off by the hand or some other conducting body before it is again placed on the plate. As the cover ought to be in a state of good insulation, the handle should be made of sealing-wax and gum-lac, or if made of glass, it should be varnished with sealing-wax dissolved in alcohol.

Sect. III.—*Description of Conductors for bringing down Electricity from the Atmosphere.*

Conductors.

Various means have been adopted for collecting the free electricity of the atmosphere, either for the purposes of experimental investigation, or in order to defend buildings and ships from lightning. The apparatus for the first of these purposes is essentially different from that which is used for the last.

1. *Electrical Kites.*

When the lower atmosphere is charged with electricity, Electrical kites.

it is not difficult to collect it for the purposes of experiment; but in ordinary states of the air, or when the free electricity exists at some height above the earth, it is necessary to bring it down by means of a kite. For this purpose a schoolboy's kite is sufficient. It is only necessary to twist a copper wire round the hempen string. Dr Franklin covered the frame of his kite with a thin silk handkerchief, in order that it might the better sustain the violence of a thunder-storm. In order to compensate for this additional weight, he made the framework of two strips of cedar wood in the form of a cross. The string of the kite terminates towards the observer in a silk string or cord, which insulates the kite and its conducting string; and in order to protect the observer still farther, a safety chain has been sometimes suspended from the extremity of the conducting string, so as to reach the ground and carry off the electricity in case of its becoming too powerful.

Mr Cuthbertson sometimes found it necessary to use three kites all connected together. On one occasion when he could collect no electricity from the atmosphere with a kite having a string 500 feet long, he succeeded in obtaining it by adding other two kites, each of which had strings of the same length. Mr Cuthbertson likewise employed an apparatus for raising his kites, in which the strings were lengthened or shortened by coiling them round a drum.

2. *Exploring Conductors.*

Exploring conductors. Read's hand-exploring rod.

One of the simplest instruments for collecting atmospherical electricity is the *hand-exploring* rod used by Mr Read. It was of the same material, length, and thickness as a common fishing-rod, and had small wire twisted round it from one end to another. Standing on an insulating stool, he raised the rod in a vertical position, and after a minute or two he touched with his other hand an electrometer, which indicated the nature and intensity of the electricity brought down. When the electricity thus obtained was very weak, he placed on the rod a lighted torch, keeping it as far up the rod as the strength of his arm would permit; and he always found that the flame attracted the electricity more powerfully than the end of the rod.

Read's fixed thunder rod. Plate CCXIV. Fig. 12.

Mr Read, however, found it necessary to use a fixed conductor or thunder-rod; and we have shown in Plate CCXIV. fig. 12, the apparatus which he used in his experiments on the electricity of the atmosphere, of which we have already given some account. The principal part of it is a wooden rod AA, twenty feet long, one inch in diameter at the top, and two at the bottom. Into the lower end of it is cemented a solid glass pillar B, coated with wax, and twenty-two inches long. This pillar rests on a wooden pedestal C, carried by a bracket D. At thirteen inches above D, the rod passes through a glass tube F, coated with wax, and supported by a strong arm of wood E. A lining of cork lies between the rod A and the tube F, to prevent the latter from being broken when the rod is bent by the wind. Several sharp pointed wires G stand out from the top of the tube. Two of them are of copper, about one eighth of an inch thick, one of them being twisted round the rod to the right, and the other to the left, as shown in the figure, so as to reach the brass collar at the top of the lower funnel H, to which they are soldered. The use of the two funnels HH is to defend the glass rods B, F from the weather. Through a hole in the wall at I passes a glass tube coated with sealing-wax, through which a strong brass wire passes from the rod at M into the room. At the end of the tube this wire passes through a brass ball L, two inches in diameter; and, after proceeding a little farther, it suspends from its extremity a pith-ball electrometer K, about twelve inches from the wall. A bell N, carried by a strong wire, is placed two inches from the brass ball L, three tenths of an inch in diameter, suspended from the nail O. The bell N, which has a metallic communication R with the moist ground, is rung by the ball L. Jars and other pieces of apparatus are placed when wanted upon the small shelf P; and all this part of the apparatus is protected from the weather by being inclosed in a wooden box.

Cavallo's atmosphe rical colle tor. Fig. 13.

M. Cavallo's apparatus, called an atmospherical collector, merits a description here, on account of its simplicity and ingenuity. A common jointed fishing rod AB, fig. 13, has its smallest joint replaced by a slender glass tube C, coated with sealing-wax. From a cork D at its outer end is suspended a pith-ball electrometer. A piece of string AHGI, is fixed to the end A of the rod, and supported at the point G by a piece of twine FG. When a pin at the end I of the cord is pushed into the cork D, the electrometer is uninsulated; but it is insulated for the purposes of observation in the following manner. The pin being fixed in the cork D, and the rod held by the hand at A, it is held out of one of the highest windows, at an angle of about 50° or 60° to the horizon, and kept there for a few seconds. The cord is then pulled at H, so as to disengage the pin from the cork D, and the string drops into the dotted position KL, leaving the electrometer insulated and electrified in a state opposite to that of the atmosphere.

3. *On Lightning Conductors.*

Lightnin conductors.

We have already seen that electricity is from various causes generated and set free in our atmosphere, and that individual clouds and masses of clouds are often highly charged with electricity, and insulated by the surrounding air. The earth and the sea are good conductors of electricity; and, generally speaking, their natural electricity is undisturbed. The attraction, therefore, of the electricity of the clouds for the opposite electricity in the earth or the sea, may become so powerful as to break through the resisting medium which intervenes. If the clouds are above a mountain or rising ground, this discharge of electric matter into the earth is attended with no danger. The effects have sometimes been traced in the fusion of portions of the rocks which crown these exposed summits. If a tree stands in the stratum of air through which the cloud discharges itself, the lightning passes through it, cleaving and bursting and damaging it in its passage. If a house obstructs its path, the electricity descends through its walls, seeking the quickest and easiest passage to the earth. It will follow bell-wires, iron rods, damp walls, and gilded pictures, and find out any matter, whether organised or unorganised, living or dead, which is placed near its path, and is capable of advancing it on its rapid and breathless errand to the earth. If a living animal grazing, or a human being walking, in an open field, intervenes between the overcharged cloud and the ground, the one or the other will become the chosen path of this irresistible foe. If a ship floats under an electrified canopy of vapour, it has less chance of escape than the tree, the house, or the living being.

The only terms upon which we can meet this relentless enemy, is a humble admission of its supreme and irresistible power, and a resolution to give it the freest and the fullest passport through our territory. We must supply it, in short, with a railway of metal, the only species of road upon which it can travel with a suitable speed and a harmless intention. The moment it ceases to find a conducting body, it begins its devastation among imperfect or non-conducting substances, till it again gets into a safe and easy path.

use con- tors.

In order to protect houses or buildings from injury by lightning, iron or copper cylindrical rods, about half an inch or three quarters in diameter, are generally fixed to the highest or most exposed parts of them. They are made sharp at the point, rise five or six feet above the most elevated part, and pass down into the ground. The iron staples which fasten them to the walls should be considerably larger than the rod, and should be covered with two or three folds of woollen cloth steeped in and covered with melted pitch. Every piece of metal on the roof should have a metallic connection with the conductor; and continuous strips of lead should be built into every wall, and connected to one another by horizontal strips communicating with the conductor.

ip con- ctors.

Although ships are especially exposed to danger, particularly in tropical climates, yet no adequate means of protection have yet been adopted, either in the royal or merchant navy. The conductors hitherto used consist of long flexible chains or links of metal about the size of a goose quill. They are sometimes made of iron, but those in the king's service are of copper. They are generally packed in a box, and when required, they are set up so as to extend from the mast-head into the sea; but it is well known that in many ships furnished with such conductors, they are kept packed up in the ship's hold during long and hazardous voyages. For this reason Mr Singer recommended that fixed conductors should be employed; that they should be attached to the mast; and that where motion is required, there should be an interruption in the inflexible conductor, and its parts should be connected "by a spiral wire, which would be at once perfectly continuous, and sufficiently flexible to yield to every necessary movement."

r Snow arris's ip con- ctors.

This important suggestion excited no attention, and it was reserved for Mr Snow Harris, F. R. S. Plymouth, to devise a new method of constructing ships' conductors, and to exhibit their utility and efficacy on board some of his majesty's frigates. In order to afford a ship effectual protection from lightning, Mr Harris conceived it to be essential that the conductor be as continuous and direct as possible from the highest points to the sea; that they be permanently fixed in the masts throughout their whole extent, so as to allow one part of the mast to move upon another; and, if any part of the mast should be accidentally or wilfully removed along with the conductor attached to it, that the remaining portion of the conductor should still be perfect, and capable of transmitting an electrical discharge into the sea. To accomplish these objects, a sort of double conductor should be formed, consisting of two laminæ of sheet copper, placed one above the other, so that the extremities of the laminæ of one layer should be opposite the middle of the laminæ of the other layer. These laminæ are each about four feet long, from six inches to one and a half broad, the thickness of the under layer being one eighth, and of the upper layer one sixteenth, of an inch. The copper bands thus formed are fixed in a fine dove-tailed groove in the aft sides of the different masts, and are secured in their place by wrought copper nails, so as to form a smooth surface, the nails being driven at each side, so as to be about four inches apart. Before inserting the conductor, the groove should be painted over with white lead, and must be deep enough to allow the copper to lie a little beneath the surface of the wood. "The metallic line," says Mr Harris, "thus constructed, will then pass downward from the copper spindle at the mast-head, along the aft sides of the royal-mast and top-gallant-mast, being connected in its course with the copper about the sheeve holes. A copper lining in the aft side of the cap through which the top-mast slides now takes up the connection, and continues it over the cap to the aft side of the top-mast, and so on as before, to the step of the mast; here it meets a thick wide copper lining, turned round the step, under the heel of the mast, and resting on a similar layer of copper fixed to the keelson; this last is connected with some of the keelson bolts, and with three perpendicular bolts of copper, of two inches diameter, which are driven into the main keel upon three transverse or horizontal bolts, brought into immediate contact with the copper expanded over the bottom. The laminæ of copper are turned over the respective mast-heads, and secured about an inch or more down on the opposite side; the cap which corresponds is prepared in a somewhat similar way, the copper being continued from the lining in the aft part of the round hole over the cap, into the fore part of the square one, when it is turned down and secured as before, so that when the cap is in its place the contact is complete. In this way we have, under all circumstances, a continuous metallic line from the highest points to the sea, which will transmit the electric matter directly through the keel, being the line of least resistance."[1]

Plate CCXIV. Fig. 14, 15, 16.

This metallic line is shown in Plate CCXIV. fig. 14, 15, 16, by the dotted line A, B, C, D; and it will be seen that any elongation or contraction of the masts, as in fig. 14 and 15, or the removal of either of them, as in fig. 16, which brings them into a new position, will in no way disturb the continuity of the line A, B, C, D, which evidently remains the same, and is therefore, under these different circumstances, the shortest and best conducting line between the mast-head at D and the sea at S. When the sliding masts are struck, a part of the conducting line necessarily remains below the cap and top; but as this is quite out of the circuit, it will not at all influence the passage of the electric fluid along the shorter line. Mr Harris has put this beyond a doubt by direct experiment.

Size of conductors.

Mr Harris has exhibited in the following table the mean proportion of a conductor thus constructed on one mast of a fifty-gun frigate, in comparison with the copper links usually furnished to the British navy, together with the equivalent of copper or of iron rod which will be necessary in order to have a conductor of the same mass. The numbers at the bottom of the table represent, with the exception of the proposed conductors, the masses, surfaces, and diameters of cylindrical metallic rods, supposed to extend the whole length of the mast. Thus, in column 2 we have 1·2 inches as the diameter, and 8064 as the surface of the copper rod, containing 2423 cubic inches of metal, and having the same quantity of matter as the proposed conductors, and from which it is calculated. The sums, therefore, are not the result of the addition of the numbers for the successive masts. The same observation is applicable to column 3, which gives the equivalent in iron. In column 4 Mr Harris has given the cubical contents and surface of a copper rod half an inch in diameter, which is supposed capable of conducting any stroke of lightning that has yet been felt; and in column 5

---

[1] "Since the mizen-mast does not step on the keelson, it will be necessary to have a metallic communication at the step of the mast, with the perpendicular stancheon immediately under, and so on to the keelson as before, or otherwise carry the conductor out at the sides of the vessel."

Electrical Apparatus.

he has given the mass and surface of the conductors now used in the British navy, which are to those proposed by Mr Harris, in reference to their cubical contents, as 94·4 to 2423, or as 1 to 257.

	2423	40176	1·2	8064	9692	16128	2·4	418	3358	94·4	1678

As the new conductors proposed by Mr Harris are composed of a series of short joints, which, whilst the continuity is still perfect, allows the conductor to bend or yield to any curvature which the mast can bear, a conductor thus applied gives great strength to a mast. In Portsmouth dock-yard, for example, it was found that the flying jib-boom of the Sapphire sloop of war would require one fifth part more weight to curve it to the same arc when the copper conductor was inserted in it. This very flexible spar was made to rest on its extreme ends, and when weights were hung to its middle point, it was made to bend like a bow, without the conductor suffering the least derangement.

It is a remarkable circumstance, that though Mr Harris has proved the excellence of his invention by its practical application to some British frigates, yet the Admiralty have not felt it their duty to introduce it into the navy. A line-of-battle ship is valued at about L.120,000, and yet it is not thought advisable to expend L.100 in defending from the most irresistible of all enemies this vast and valuable machine, and in protecting the lives of the thousand brave men that live within its walls.

CHAP. II.—DESCRIPTION OF INSTRUMENTS FOR ACCUMULATING, CONDENSING, AND MULTIPLYING ELECTRICITY.

Instruments for accumulating electricity.

The instruments which have been employed for the purposes of accumulating, condensing, doubling, and multiplying electricity, may be divided into four classes:

1. Jars and batteries.
2. Condensers.
3. Doublers.
4. Multipliers.

SECT. I.—*On the Construction and Action of Jars and Batteries.*

Jars and batteries.

By means of the prime conductor of an excited electrical machine, we can obtain electricity in sufficient quantity and intensity for many important researches; but when we wish to accumulate it in great quantities, and to obtain a powerful charge, it is necessary to employ the Leyden phial or jar; and by increasing the number of jars, and uniting them together, we can accumulate electricity to an unlimited extent.

ectrical paratus.

ectrical CCXV. . 1.

An electrical jar, in its best form, is shown in Plate CCXV. fig. 1, where AB is a glass jar, having its lower end CDEB coated both on the outside and the inside with tinfoil, which is made to adhere to the glass by means of gum water. The jar should have no cover, as it generally has, but the charge is conveyed to the bottom of the jar by a copper tube FGH, three eighths of an inch in diameter. This tube terminates in a ball, F, of baked wood, and is kept in its place by a convenient foot, firmly cemented to the bottom of the jar, which is previously covered with a circle of pasted paper, leaving a central portion of the coating free for the perfect contact of the charging rod FGH, which passes through the centre of the foot, as shown by the dotted lines in the figure.[1] When the jars are either employed singly, or united so as to form a battery, they should be placed on a conducting base, supported by short columns of glass, or some other insulating substance, such as rosin or brimstone, so that the whole can be insulated when necessary.

. 2.

In order to allow the jars to be charged and discharged with precision, Mr S. Harris connects them with what he calls two centres of action, A, B, shown in fig. 2. The first of these, A, consists of a brass ball, which slides with friction on a metallic rod AD, so as to admit of its being placed at any required height. This ball has a number of holes perforated in its circumference, to receive the points of the rod or rods which connect it with the jar or jars. The rod AB which supports this ball may be either insulated on a separate foot, and connected with the prime conductor, or it may be inserted directly into it. The second centre of action consists of a larger ball of metal, B, attached to a firm foot, and placed on the same conducting base with the jar, so as to be perfectly connected with it. When the first centre of action, A, requires to have a separate insulation, the insulating glass rod is screwed immediately into the lower ball B, and sustains the metallic rod above described, by the intervention of a ball of baked wood, D, the opposite end of the rod terminating in a similar ball, C, through the substance of which the conducting communication with the machine passes when it is placed on a separate foot. All the metallic connection should be covered with sealing wax, except at the points of junction, and the wooden balls and different insulations should be carefully varnished.

ectrical tery. . 3.

A battery constructed in this manner, and containing six jars, is shown in fig. 3, A and B being the two centres of action, and C and D the two balls of baked wood, as shown in fig. 2. The communication with the prime conductor is made by a wire CE passing through the ball C, and the jars communicate with the centre of action A by means of wires entering the ball A, as shown in the figure.

In order to charge the jar shown in fig. 1, it is only necessary to make the copper tube FG communicate with the prime conductor of the electrifying machine by means of a wire passing through F. It was formerly the custom to make the copper rod HG terminate above in a brass ball at F; and when this was the case the jar could be charged by bringing the ball F near the conductor, or by holding the jar by the outside coating, and bringing the brass knob close to the conductor.

Electrical Apparatus.

Discharging rods. Fig. 4.

When the jar is fully charged, it may be discharged by holding the outside coating in one hand, and touching with the other the copper tube FG, or the ball F if it is a brass one; but in this case the person will receive a shock, the electrical charge passing into his body. The jar may be discharged without receiving a shock, by a very simple instrument, called a *discharging rod*, shown in fig. 4. It consists of two bent wires BC, BD, having a brass ball C and D at each end, and uniting at B, where they are fastened at their common junction into a glass handle AB. The operator takes hold of the glass handle, and placing the lower knob D on the outside coating of the jar, and the upper knob C in contact with the copper wire FG, or the brass ball at F, if there is one, the discharge takes place with a loud snap the instant that the knob C touches F.

Fig. 5.

A more convenient form of discharging rod is shown in fig. 5, where the two balls C, D, and the branches CE, DE, correspond to the balls C, D of the branches CB, DB, in fig. 4; but in place of attaching one insulating glass handle to the joint E, a separate glass handle, viz. A and B, is attached to each branch. By this means, by taking the handle A in one hand, and B in the other, we can open the balls C, D to the required distance without touching the metallic branches CE, DE, and also with greater facility and certainty.

If the jar is connected with the piece of apparatus BC, fig. 2, so that the centre of action A communicates with the internal coating of the jar, and the centre of action B with the external coating, then the jar will be discharged by making the knob D of the discharging rod touch B, while the knob C touches A. In like manner the whole battery in fig. 3 may be discharged by making the knob D of the discharging rod touch B, while the knob C touches A.

Henley's universal discharge. Pl. CCXV. Fig. 6.

A general instrument for discharging jars and batteries, invented by Mr Henley, has been much used, particularly in the deflagration of metals by electricity. It is shown in fig. 6, where A and B are insulating glass pillars, cemented into a wooden stand. A brass cap with a horizontal and vertical motion is fixed on the top of each of these pillars; and at the top of this joint is a spring tube, through which the handles D or C can be slid backwards or forwards. These handles are made of strong brass wire, terminating at one end in a ball, or point, or a pair of forceps, and at the other in a solid glass rod for an insulating handle. A small wooden table F, about five inches in diameter, has a slip of ivory glued into its upper surface, and may be raised or depressed in its socket by the screw-nut G. Sometimes a small mahogany press accompanies the instrument. It consists of two boards, which can be pressed together by two nuts, and is put into the socket in place of the table F, when it is necessary to fix or hold steady the body through which the discharge is to be passed. The body to receive the charge must either be laid on the table or fixed in the press, or held between the balls, points, or forceps. The two sides of the jar or battery are then connected with the two brass caps at the tops of the pillars A, B; and, by means of the insulating handles, the distance is regulated through which the charge has to pass.

This instrument was originally constructed without any insulating handles; and the wires, and the handles C and D, were thick brass wires, terminating on one side in a ball or point, and on the other in a ring of brass, with which the connection with the jar or battery was formed.

Coated plates of glass.

Although it has proved advantageous to use jars for receiving and accumulating electricity, yet this form of the recipient is by no means essential. The very same effect is obtained if a plate of glass is coated on both sides within an inch of its edges; for a jar may be considered as a plate of glass rolled up into a cylindrical form. Hence a battery may be composed of a number of coated plates of glass; and it was actually with one of this kind, consisting of eleven panes of window glass, that Dr Franklin performed most of his experiments.

---

[1] The method of constructing the jars and batteries here described is that used by Mr Snow Harris, and described in his valuable paper on the Laws of Electrical Accumulations.

Theory of the Leyden phial.

Dr Franklin was the first person who explained the principle upon which the action of the Leyden jar depends. He began by examining the electricities of the inside and outside coatings. A cork ball suspended by a silk thread was attracted by the outside and repelled by the inside coating. When the jar was charged with the opposite electricity, the ball was repelled by the outside and attracted by the inside coating. Hence it follows that *the outside and inside coatings of a Leyden jar are charged with opposite electricities.*

When the inside coating was charged from the prime conductor, its electricity was positive, while that of the outside was negative; but when the outside of the jar was charged from the same conductor, the outside was positively electrified, and the inside negatively, and the charge was as strong as before.

In order to show that the negative electricity of the one coating was equal to the positive electricity of the other, Dr Franklin hung a small linen thread near the outside coating of a charged jar, and every time that he touched the knob or wire of the jar the thread was attracted by the coating, the electricity taken from the inside by the finger being equal to what was drawn in on the outside by the thread. He then repeated this experiment when the jar was placed upon an insulating stand, and he found that at every successive contact a portion of the electricity of the outside became free, and the linen thread sprang to the outside coating to receive and carry off the superfluous electricity.

Experiment to show the equality of the two electricities.
Fig. 7.

The equality of the two electricities is still more clearly evinced in the fine experiment of Professor Richman, shown in fig. 7. Having coated with tinfoil the opposite sides of a plate of glass AB, to within two inches of its edges, the glass was then placed vertically, and a linen thread *m* was suspended to the upper part of each of the two coatings. When the plate was not charged, the two threads hung down parallel to each other, and touched the tinfoil; but when the plate of glass was charged, the threads were repelled from the glass, and formed equal angles with it on both sides. When any conducting body, such as the finger, was brought near one coating, the thread on that side sunk, and formed a less angle with the glass, while the thread on the other side rose to a greater angle, the augmentation of the angle on one side being exactly equal to its diminution on the other. When the finger touched one coating, the corresponding thread fell down entirely, and the thread on the other side rose to a double elevation, so that the angle formed by the two threads was a constant quantity, depending on the intensity of the charge communicated to the plate.

The next point of inquiry to which Dr Franklin applied himself, was to ascertain where the two electricities resided, and what was the function performed by each coating. Having charged a jar, and placed it on an insulating stand, he took out the ball F, and rod FH, fig. 1, and found that they did not contain any electricity. He then touched the outside coating with one hand, and putting the finger of another hand into the mouth of the bottle, he received a shock as powerful as if the ball and rod FH had been in their place. He next put into the phial some clean water, which, being a conductor, answers the same purpose as tinfoil, and having charged the jar, and poured out the water into an insulated bottle, he found that it would not give the shock. Upon filling the phial with fresh water, and without giving any new charge to the jar, he received a shock as at first, which clearly proved to him that the electricity resided in the glass. This important truth may be clearly established in the following manner:—Take a cylindrical jar, and let the outside and inside coatings of tinfoil be nicely fitted, and applied to the surface without any cement. When this jar is charged in the usual manner, place it on an insulating stand or a glass plate, and holding it by the uncovered part, lift out the interior cylinder of tinfoil without injuring its shape, and then lift the glass cylinder out of its exterior coating. If we now touch the outside of the glass cylinder with one hand, and at the same time the inside with the other, we shall obtain no perceptible shock. In like manner, no shock will be experienced by touching the outside coating of tinfoil with one hand, and the inside with the other, nor by touching either separately. But if the two coatings are again replaced on the glass cylinder, the one on the outside and the other on the inside, a shock will be obtained in the usual way. Hence it follows, as Dr Franklin concluded from the same experiment in another form, that the electricity is accumulated on the surface of the glass, and that the metallic coatings, or other conducting substances, which are placed in contact with both sides of the glass, perform only the function of forming a perfect communication between every point of the external with every point of the internal surface of the glass at the instant of the discharge.

Theory of the Leyden jar.

In order to explain the theory of the Leyden jar, let us place a jar AB uncharged upon an insulating stand CD, and make its outside coating B communicate with a pair of insulated pith balls *m*, *n*, as shown in fig. 12. From the prime conductor convey a few sparks of positive electricity to the jar by the knob F, the pith balls *m*, *n* will diverge with positive electricity, owing to the decomposition of the natural electricity of the external coating. If we now touch the pith balls, the positive electricity which made them diverge will escape, and they will fall into their natural vertical position. But we have not thus removed all the positive electricity which was communicated to the interior coating. A portion of it has become fixed or latent, which can only happen from the influence of a portion of resinous electricity. If we now touch, indeed, the brass ball F, the portion of positive electricity which remains free in the inside coating will cause the pith balls communicating with the outside coating to diverge with negative electricity.

If, when the pith balls are divergent with positive electricity supplied from the conductor, we touch them so as to allow it to escape, the repulsive force which it exerted on that in the interior coating will cease, and the ball F and the interior coating will be capable of receiving an additional quantity from the conductor. The pith balls will again diverge with positive electricity; and if this be again removed, the ball F will again be able to receive a farther supply from the conductor, so as to make the pith balls again diverge. The interior coating will be receiving more and more positive electricity, till its repulsive power becomes so great as to resist the introduction of any more. The jar is now charged, and will give a shock in the usual manner, or may be discharged by the discharging rod. Hence we may conclude that the positive electricity introduced into the inside coating of the jar decomposes the natural electricities of the outside, drives away from it the positive and fixes the negative electricity, which, by its reciprocal attraction, fixes also a part of it in its turn.

From the principles above established, it may be shown that a given quantity of electricity from the prime conductor may be made to charge two or more jars almost as powerfully as if the whole quantity was communicated to

CCXV. g. 9.

one jar only. The jars being placed as in fig. 9, the electricity from the prime conductor is conveyed by a chain A to the ball B of the first jar. The ball F of the second jar has a similar connection with the coating of the first, and by a third chain the coating of the second jar is connected with the earth. When the inner coating of the first jar receives positive electricity, the outer coating has its natural electricity decomposed; the negative portion is fixed by the influence of the positive electricity within, and the positive portion is repelled to the interior of the second jar, where it does the very same thing which was done by the same electricity within the first jar. The positive electricity set free at the exterior of the second jar is repelled to the earth, and any requisite portion of negative electricity is conveyed to the outer coating of the same jar, in order to fix by its influence the positive electricity which arrives at the interior of the jar. If we now remove all the connections, the two jars will have received their full charge; and the same will take place with any number of jars similarly arranged for the purpose.

As the accumulation of electricity in a jar depends upon the mutual attraction of the two electricities, and as this force varies inversely as the square of the distance of the molecules, the intensity of charge which any jar can receive should increase with the thinness of the glass which separates the two fluids. Mr Cavendish inferred from his researches, that the intensity of the charge was inversely as the thickness of the glass; but we cannot avail ourselves of this principle in practice, as a certain thickness of glass is necessary to the due strength of the jar; and it has been proved by experiment, that when the glass is thin, the mutual attraction of the two electricities has been capable of forcing a passage through the glass itself. The common glass jars, therefore, are as thin as they can be made with perfect safety. Mr Brooke always placed a layer of paper between the tinfoil and the glass, for the purpose of enabling the jar to contain a charge of greater intensity.

vallo's lf-charg- g jar.

Before concluding this section, we shall describe a pretty little instrument invented by M. Cavallo, called the *self-charging jar*. Having procured a glass tube eighteen inches long and one and a half inch in diameter, coat one half of the inside of it with tinfoil, and close the aperture of the coated end with a cork, through which there passes a wire touching the inner coating, and terminating in a brass ball fixed at the uncoated end of the tube. If we now hold the uncoated part of the tube in one hand, and rub the outside of the coated part with the other, and after every three or four strokes touch with the rubbing hand the brass knob or ball, the hand will communicate to it a spark, and the inside coating will thus be gradually charged. If we now grasp the outside of the coated end with one hand, and with the other touch the brass ball, we shall discharge the tube and receive a shock.

SECT. II.—*On the Construction of Condensers of Electricity.*

ndensers electri- y. CCXV. g. 10.

An apparatus for condensing electricity in a conducting body was the undoubted invention of M. Æpinus, who also gave the true theory of its action. Volta, however, had the merit of first applying it to an electrometer for indicating small quantities of electricity.

The condenser shown in fig. 10 consists of two separate parts, the first of which is a metallic disc B, supported by a metallic stand BD, and the second is a similar disc A, having a glass handle C rising from its tube, and a small metallic pin and knob P projecting from its circumference. The upper surface of the plate B and the lower surface of A are covered with a thin film of a non-conducting substance, such as varnished silk, rosin, or glass. If it is now wished to condense any feeble electricity from any body, as, for example, from a feebly electrified conductor, bring the metallic pin P into contact with the body or electrified conductor; and while it is in contact let the metallic disc B be brought close under it, as in the figure, the varnished surface of A resting on the varnished surface of B. In this state withdraw the whole from the prime conductor; and having removed the plate B, apply the plate A to two suspended pith balls, which will separate to a very considerable angle in consequence of the electricity having been condensed by the contact of the disc B. That this is the case may be readily proved by applying A to the pith ball before the disc B was joined to A, when their divergence will be greatly less than before. The explanation of this is very simple. The positive electricity, for example, conveyed by the prime conductor to the plate A decomposes the natural electricity of B. The positive portion of B is repelled to the earth by the similar electricity in A, while the negative portion is attracted to the upper surface of B by the opposite electricity in A. In this position it is capable of attracting to the inner surface of A an additional quantity of the free electricity in the prime conductor; and this additional quantity will in its new position produce a farther decomposition of the natural electricity of C. All these effects will take place simultaneously till an equilibrium is established between the free positive electricity supplied to A by the prime conductor, and the negative electricity which the attractive force of this electricity can draw from the earth.

It is manifest, from these observations, that the principle of the condenser is exactly the same as that of the Leyden jar. The upper disc A which receives the electricity corresponds with the inner coating of the jar, the under disc C with the outer coating, and the film or films of rosin, &c. with the glass of the jar.

Volta's condensing electrometer. Fig. 11.

The condensing electrometer of Volta is shown in fig. 11, where CAB is the condenser above described. From the lower side of the plate B are suspended, by two metallic wires, two perfectly even and straight straws *m*, *n*, and on the mouth of the bottle DEFG is fixed the disc B, so that the two straws hang freely in the axis of the neck of the bottle. A graduated circle *op* is pasted on the outside of the bottle, to estimate the angular separation of the straws, which affords a mean of the electricity condensed in the manner already described.

Cuthbertson's condenser. Fig. 12.

Mr Cuthbertson's condenser, shown in fig. 12, consists of two flat circular plates of brass A, B, about six inches in diameter. The receiving plate A is supported by a glass pillar, firmly fixed to a wooden stand, while the condensing plate B is sustained by a brass pillar, but so as to move round a joint at its lower end, in order that it may be thrown back into the dotted position shown in the figure. When the plates stand parallel and vertical, the receiving one A is connected by a wire with the body whose electricity is to be condensed. In this state it is allowed to continue for a short time, when the wire is removed and the plate B thrown back into the dotted position. The electricity will then be found condensed in the plate A.

Fig. 13.

When this instrument is applied to an electrometer, as in fig. 13, it forms an excellent condensing electrometer; and the effect may be greatly increased by uniting Cuthbertson's condenser with that shown in fig. 13. This may be done by merely uniting the moveable plate of the former to the fixed plate A of the latter by a small brass pin.

Nicholson's spinning condenser. Fig. 14.

Nicholson's spinning condenser, which is a very ingenious instrument, is shown in fig. 14, where A is a metallic vase, which revolves about a steel axis EK, whose pivot K runs in the adjustable socket C at the bottom of the stand H; a circular disc of glass D, one and a half inch in diameter and two tenths thick, is fixed to the vase A, and revolves along with it, while a similar plate E is fixed on the top of the stand H. These two discs are shown separately in fig. 15. In the edge of the plate E are drilled two holes to receive metallic hooks F, G, and into the edge of the upper plate D are cemented two small tails of the flattened wire used in making silver lace. These tails are bent down so as to strike the hooks F, G during their revolution, without touching the rest of the apparatus. The two adjacent faces of the glass discs are coated with segments of tinfoil, as shown in fig. 15; and they may be set at any distance by means of the screw C. Each tail communicates with the tinfoil coating of D; the hook F communicates with that of E, but the hook G is insulated so as to communicate only with the electrified body. The coating of E communicates with the earth by means of the stand H.

Fig. 15.

If the vase A, the plate D, and the axis EK, are now set a spinning by the action of the finger and thumb applied at T, one of the tails will strike the hook G, and receive through it from the electrified body some of its electricity, which it will convey to D, which will thus assume the electric state of the body. The tail which has struck G proceeding onwards, will after half a revolution touch F, and will convey the free electricity received at G to the two coatings, which with the hook F constitute one insulated mass. The tail advances, acquires more electricity from G, deposits it at F, and thus condenses it, on the principle of the common condenser, till it is capable of affecting the pith balls at F. The instrument constructed by Mr Nicholson was five inches high, and condensed very small degrees of electricity.

SECT. III.—*On the Construction of Electrical Doublers.*

Electrical doublers.

This class of instruments operate by continually doubling small quantities of electricity till the common electrometer is capable of indicating its presence and qualities.

Bennet's doubler. Pl.CCXV. Fig. 16.

The doubler invented by Mr Bennet consists of three plates, A, B, and C, fig. 16. The plate A, which is of brass, has an insulating handle rising from its centre; the plate B, which is also of brass, has a similar handle fixed in its circumference. The third plate, C, also of brass, is placed on Bennet's gold-leaf electrometer. The under side of A, the upper side of C, and both sides of B, are varnished. The body whose electricity it is required to double is brought into contact with the under side of C, which rests on the cap of the electrometer, while B is touched with the finger of the other hand. The communication with the electrified body being broken off, B is lifted up by its glass handle. If the electrometer leaves do not diverge, A is placed by its handle upon B, thus lifted up; and A being now touched by stretching a finger over the juncture of its insulating handle and immediately withdrawing it, A is separated from B. In this situation two of the plates have obviously nearly equal quantities of one kind of electricity, while the third plate has the opposite kind. The plate A is then made to touch the under surface of C, resting on the electrometer, and at the same time C is covered with B. The plate B is now touched by the finger as A was; and removing A, and withdrawing the finger from B, and lifting it up from C, the electricity is doubled. By repeating this operation ten or twenty times, which may be done in forty seconds, the electricity will, by continual duplication, be augmented 500,000 times. When sparks are required, C must rest on an insulating stand in place of the electrometer.

It was found by Mr Bennet, Cavallo, and others, that the doubler became strongly electrified even when no electricity was communicated to it. To remove this evil, M. Cavallo used three plates without varnish, and he placed them on insulating stands, so as to have a vertical direction, and to stand within one eighth of an inch of each other, the plates of air being a substitute for the varnish. The method of doubling is exactly the same as before. Dr Robison adopted the same idea, but he kept his plates horizontal, making them rest on each other by three small spherules of glass or sealing-wax. Notwithstanding these precautions, however, electricity was still produced.

In order to perform the operation of doubling with more rapidity, Dr Darwin proposed the *moveable doubler*, or one in which the plates could be moved by wheel-work into their proper positions. Dr Nicholson improved upon this idea by producing the whole effect with the simple revolution of a winch.

Nicholson's revolving doubler. Fig. 17.

This *revolving doubler*, as it has been called, is represented in fig. 17. It consists of two fixed plates of brass A, C, two inches in diameter, insulated separately, and placed in the same plane, so that a revolving plate B may pass near them without touching. A brass ball D is fixed on the end of the axis which carries B, and is loaded within at one side so as to counterpoise the plate B, and allow it to rest in any position. The axis PN, and the axes that join the three plates with the brass axis NO, which passes through the brass piece M, by which the plates A and C are supported, are made of varnished glass. One end of this axis carries the ball D, and the other is connected with a rod of glass NP, upon which the handle L is fixed, and also the piece GH insulated separately. The pins E, F rise from the back of the plates A, C, at equal distances from the axis. The arm K is parallel to GH, and the ends of both are armed with pieces of harpsichord wire, so as to touch the pins E, F in certain points of their revolution. A pin I is fixed on M to intercept a small wire proceeding from the revolving plate B. These wires are so bent that, when B is opposite to D, GH connects the two fixed plates A, C, while the wire and pin at I connect the ball D and plate B. On the other hand, when B is opposite C, D is connected with C by the contact of F with the wire at K, the plates A, B being then entirely unconnected with any other part of the instrument. In all other positions the three plates and the ball D will have no connection with each other. The operation of this instrument is thus described by Mr Nicholson: "When the plates A and B are opposite to each other, the two fixed plates A and C may be considered as one mass, and the revolving plate B, together with the ball D, will constitute another mass. All the experiments yet made concur to prove that these two masses will not possess the same electric state; but that, with respect to each other, their electricities will be *plus* and *minus*. These plates would be simple, and without any compensation, if the masses were remote from each other; but as that is not the case, a part of the redundant electricity will take the form of a charge in the opposed plates A and B. From other experiments, I find that the effect of the compensation on plates opposed to each other at the distance of one fortieth part of an inch is such that they require to produce a given intensity, at least a hundred times the quantity of electricity that would have produced it in either singly and apart. The redundant electricities in the masses under consideration will therefore be unequally distributed; the plate A will have about ninety-nine parts, and the plate C one; and for the same reason the revolving plate B will have ninety-nine parts of the opposite electricity, and the ball D one. The rotation, by destroying the contacts, preserves this unequal distribution, and carries B from A to C, at the same time that the tail K connects the ball with the plate C. In this situation the electricity in B acts upon that in C, and produces the contrary state by virtue of the communication between C and the ball; which last must therefore acquire an electricity of the same kind with that of the revolving plate. But the rotation again destroys the contact, and restores B to its first situation opposite A. Here, if we attend to the effect of the whole revolution, we shall find that the electric states of the respective masses have been greatly increased; for the ninety-nine parts in A and in B remain, and the one part of electricity in C has been increased so as nearly to compensate ninety-nine parts of the opposite electricity in the revolving plate B, while the communication produced an equal mutation in the electricity of the ball. A second rotation will of course produce a proportional augmentation of these increased quantities, and a continuance of turning will soon bring the intensities to their maximum, which is limited by an explosion between the plates."

onalds' ndulum ubler. l. CCXV. ig. 18.

An ingenious instrument, called a *pendulum doubler*, has been recently constructed and described by Mr Ronalds. Having found it necessary to keep a telegraphic wire constantly electrified with a very small source of electricity, he converted the bob of a pendulum into the centre plate of a doubler, and he found the instrument thus modified not only useful for that purpose, but also for that class of experiments, such as those on vegetation and animal life, which require a constant supply of small quantities of electricity to supply the loss occasioned by unavoidable defective insulation, either in the glass which is used, or in the surrounding atmosphere. This improvement on the doubler is shown in fig. 18, where A and B are the two fixed plates, about four inches in diameter, supported by glass pillars; C is the bob carried by the pendulum rod D, and insulated by the piece of glass e. The form of the bob C is that of a plano-convex lens, with its interior filled with lead; e is a small cylinder connected to C with screws, which also adjust the plane of C parallel to the plane of vibration; g is another insulating glass rod, carrying the bent wire h, the left end of which lies nearly in the same vertical plane as the end of the wire m, the right end being nearly in the same plane as the end of the wire n. A wire, i, rises perpendicularly from C; and another, k, perpendicular to the plane of vibration, is fixed into the brass cup at the end of the pendulum rod. A wire, l, is screwed into the edge of the plate B, and the long wire m is fixed on the lower edge of B, so as to approach within a small distance of A, where it is bent at right angles, and then projects in a plane perpendicular to that of vibration. Another wire, n, is fixed into the edge of A, so as to bend and project similarly; but n projects farther than m, that the right side of the bow k may pass the end of m without touching it. A wire, o, is fixed at right angles into the base of the instrument.

When the bob C is exactly opposite A, the insulated wire h touches simultaneously the ends of the wires m and n, and establishes a communication between A and B, while at the same time the wire i, by touching o, forms a communication between C and the ground. Now, if a quantity of *positive* electricity, for example $= 1$, is given to A or B when the centres of A and C are opposite to each other, that quantity will be nearly all condensed on A, and C will acquire *negative* electricity nearly $= 1$.

"If C," says Mr Ronalds, "be now allowed to begin its vibrations, the connection of A and B with each other will be instantly broken, as also that of C with the earth, and they will be all insulated, and all retaining the electric states which they possessed before the connections were broken (*i. e.* A will be positive nearly $= 1$, B negative nearly $= 1$, and C positive almost 0).

"When C has arrived opposite B, the *uninsulated* wire k will touch the wire L, and thus place B in connection with the earth; therefore C, by virtue of its negative charge, will induce a positive charge in it nearly $= 1$.

"When C arrives a second time opposite to A, all the former connections will be re-established, and the charge of B will (by means of the wire m) be nearly all condensed on and added to the original charge of A, making a tension nearly $= 2$ of positive electricity, which tension will induce a tension of nearly $= 2$ of negative electricity on C.

"And so the charges in A and C would go on, nearly *doubling* at each vibration of the pendulum, until their tensions would arrive at such a point as to cause a spark to pass between them.

"But P is a Leyden jar furnished with a Lane's discharging electrometer q; a connection is established by means of a small chain between it and A; and the distance between the two balls r and s is considerably less than that between A and C; therefore the spark will be given to the jar, and a spark will be continued to be given at the completion of almost every second vibration, until it is charged almost as highly as A is capable of being charged, or the sparks will continually supply the loss of electricity by any defect of insulation, either of the jar, or of any conducting body in connection with its interior coating within certain limits.

"The contacts of the wires do not impede the velocity of the vibrations, because they are made small enough to act as springs of a required force; but the electric attractions of the plates and bob *do* tend to do so. The pendulum is suspended by two springs, placed one at each extremity of a cross piece, to which the rod is attached, for the purpose of preventing the bob from being drawn, by their attractions, out of its assigned plane of vibration as much as possible."

SECT. III.—*Description of Instruments for Multiplying Electricity.*

Multipliers of electricity. Cavallo's multiplier. Plate CCXV. Fig. 19.

The electrical multiplier invented by M. Cavallo is shown in fig. 19, on a scale about one third of its real size, and is chiefly useful in ascertaining the presence of a considerable quantity of electricity occupying an extended space. Its principal parts are four plates of brass A, B, C, D. The plates A, C are supported by two glass rods G, H, fixed in the wooden base R, S, Q. A similar plate B is supported by another glass rod I, cemented into the wooden lever LK, moving round a pivot K. The fourth plate D is supported by a metallic rod. By the lever KL the plate B can be moved from its position on the figure into the dotted position KX. The plate D is screwed at P into a piece of brass FP, which slides in a groove, so that D can be pulled out to any distance from C. At the corner Q is fixed a brass rod N, and Om is a small bent wire fixed to the brass socket O on the back of B. When B is as near as possible to A, their distance being one twentieth of an inch, this wire m touches the rod N, and forms a communication with the earth; when FP is pushed in as far as possible, the surfaces of C and D are one twentieth of an inch distant. As the lever KL moves towards X, the end m of the wire mO quits N and insulates the plate B; and when the lever has the position KX, the wire m will touch the plate C, so as to put the insulated plates B into communication with each other.

If a body weakly electrified positively is now made to touch A, when A and B are placed together as in the figure, A will acquire a greater quantity of positive electricity from the presence of the uninsulated plate B, which will be negatively electrified. When KL comes into the position KX, so that B touches C by the wire *m*O, its negative electricity will pass almost wholly to C, owing to its proximity to D, which communicates with the ground. By a number of successive oscillations of the lever between the two positions KL and KX, this operation may be repeated till an accumulated charge of negative electricity has been fixed upon C. The plate D must now be drawn away from C by means of the slider FP, and if pith balls are presented to C they will diverge with negative electricity.

Schweigger's multiplier.

In our chapter on the chemical agencies of electricity, we have already described Schweigger's multiplier or galvanometer, which was used by M. Colladon in his experiments on the chemical action of ordinary electricity; and also the multiplier of Dr Faraday with a double helix, which he employed in his researches on the identity of the electricity of the machine with that of the pile. Various improvements have been made on the multiplier by M. Nobili, Professor Oersted, and others; but we must reserve our account of them for the articles GALVANISM and MAGNETO-ELECTRICITY.

CHAP. III.—DESCRIPTION OF INSTRUMENTS FOR INDICATING THE PRESENCE OF ELECTRICITY, AND MEASURING ITS QUANTITY.

Indicators and measurers of electricity.

Instruments which are intended merely to indicate the presence of electricity are called *electroscopes*, while those which are intended for measuring the quantity of electricity are called *electrometers*. The earliest electrometer which seems to have been employed was a pair of silk threads, which indicated the presence of small quantities of electricity by their divergence; and the Abbé Nollet even attempted to measure the quantity communicated to them, by determining the inclination of the two threads, from their shadow on a board. Mr Waitz improved the instrument by suspending small weights to the threads, and Mr Canton perfected it by substituting the finest linen threads for the silk ones, and by suspending from them a pair of small balls turned out of the dry pith of the elder.

Description of Cavallo's Electroscope.

Cavallo's electroscope. Plate CCXVI. Fig. 1.

M. Cavallo made this little instrument portable by fitting it up as in fig. 1, where it is shown in a state of action at B. When it is unloosed, the end B carrying the pith balls is screwed off, and the balls are put into the glass tube at A, which serves for a handle. This glass case is three inches long and three tenths of an inch wide, and half of it is coated with sealing-wax. A cork tapering at both ends is made to fit the mouth of the tube, and to one end of the cork are fixed two linen threads carrying two small cones of elder pith. The case of the electrometer at C incloses at one end a piece of amber for giving negative electricity, and at the other end a piece of ivory insulated upon a piece of amber for giving positive electricity, to the balls, when rubbed with a piece of woollen. All these instruments may be greatly improved by substituting for the pith of elder the pith of the sola, a tree which grows in the East Indies.

Description of Bennet's Gold-Leaf Electrometer.

Bennet's gold-leaf electrometer. Fig. 2, 3.

One of the most useful electrometers is that which was invented by Mr Bennet, and called the gold-leaf electrometer. This instrument, which is shown in fig. 2, and a section of it in fig. 3, consists of a cylinder, ABED, with a broad brass cap, AB. In a hole, *a*, in the centre of the cap, is fixed a wedge of wood, on each side of which is fastened by a little varnish a smooth-edged strip of gold leaf, shown at *m* and *n*, about two inches long and a quarter of an inch broad. Two pieces of tinfoil, *b*, *c*, are pasted opposite each other, and within the cylinder, so as to rise a little higher than the ends of the gold leaves, and the lower ends of these pieces of foil are in contact with the brass stand DEF which sustains the instrument. The inside of the cap AB, and the upper part of the glass cylinder, are sometimes coated with wax. A pointed wire, C, is used to collect the electricity of the atmosphere. In using this instrument, the cap AB is turned round till the surfaces of the gold leaves are parallel to those of the pieces of tinfoil. When no electricity is present the two gold leaves hang in contact in the axis of the cylinder; but if a fully electrified body is made to touch the cap AB, the gold leaves *m*, *n* will diverge as in the figure, and their lower ends will strike the pieces of tinfoil *b*, *c*, which will convey the electricity to the ground.

Mr Nicholson has proposed to substitute two flat radii of brass in place of the tinfoil, and by moving them to and from the gold leaves with a micrometer screw, to make the instrument more sensible, and at the same time obtain a kind of measure of its quantity.

Singer's Improved Electrometer.

Singer's improved electrome ter. Plate CCXVI. Fig. 4, 5.

Although insulation may be procured by coating glass insulators with wax, yet, as Mr Singer observes, this affords only a temporary defence, as moisture is eventually precipitated upon them; and in removing this it is almost impossible to avoid exciting the surface of the wax, and disturbing delicate experiments by the electricity which is thus generated. To remove this evil Mr Singer proposes to inclose the insulator in a narrow channel, as the moist air in contact with it would be then limited in quantity, and little disposed to motion. In applying this principle to the improvement of Bennet's electrometer, the insulation is effected by a glass tube four inches long and one fourth of an inch internal diameter, coated out and in with sealing-wax, and having a brass wire five inches long and one sixteenth or one twelfth of an inch thick to pass through its axis, so as to be perfectly free from contact with any part of the tube, in the middle of which it is fixed with a plug of silk, which keeps it concentric with the internal diameter of the tube. This arrangement is shown in fig. 4, 5, where A is a brass cap screwed upon the upper part of the wire *w*, which prevents the atmosphere from having free contact with the outside of the tube B, and defends at the same time its inside from dust. To the lower end of the wire the gold leaves are fastened, and the glass tube passes through the centre of the usual cap of the electrometer, and is cemented in it near the middle of its length, as may be seen by the dotted lines which represent the cap. "When this construction," says Mr Singer, "is considered, it will be evident that the insulation of the wire, and consequently of the gold leaves, will be preserved until the inside as well as the outside of the glass tube is coated with moisture; but so effectually does the arrangement preclude this, that some of those electrometers that were constructed in 1810, and have never yet (1814) been warmed or wiped, have still apparently the same insulating power as at first." The electrometer constructed upon the preceding principles is shown complete in fig. 5.

Fig. 4, 5

Fig. 5.

Dr Fara day's in structio for usin electrom ters.

Dr Faraday recommends strongly the use of this electrometer; but having found from repeated experience that its indications are not in general well understood by those who have occasion to use it, he has given a very valuable description of the kind of charge which it receives under different circumstances, and the precautions which are necessary in interpreting its indications. As this description would lose its value by any abstract or alteration, we shall make no apology for giving it in his own words, especially as it is applicable to many other analogous instruments.

"If an insulated portion of conducting matter, as a brass ball at the end of a glass handle or silken thread, be electrified, and then placed in *contact* with the cap of the electrometer, the cap and leaves will immediately partake of the electricity of the ball, and the leaves will diverge. If the charge in the ball be of considerable intensity, the leaves will be torn to pieces by their mutual repulsion, and the attraction of the sides of the glass jar; but if the intensity be small, the leaves will diverge moderately, so as not to touch the glass, and the degree of divergence will be in some proportion to the intensity of the charge communicated. The appearances will be the same whether the electricity communicated be positive or negative.

"The circumstances will be different if the body brought in contact with the electrometer is an electrified portion of what is usually called non-conducting matter; if, for instance, it be a stick of sealing-wax rubbed with flannel, instead of a metallic ball. If highly electrified, this will cause the same disturbance and appearance in the leaves during its approach as the ball; if moderately electrified, it will, when in contact with the cap, cause the usual appearance of divergence in the leaves, but upon removing it, the leaves, instead of remaining diverged, will either collapse, or remain very slightly, and frequently uncertainly, electrified. This is a consequence of the non-conducting power of the wax; and the method of transferring electricity to the electrometer in such a case is, to draw the excited parts of the wax over the edge of the cap; small portions will be communicated, and the electrometer will be left electrified similarly to the wax. Such a process is, however, very uncertain; for if the electricity of the wax be weak, the friction of the substance against the electrometer cap will sometimes generate an electricity stronger than that previously existing on the surface of the wax, and the electrometer will become charged, not by the previous electricity of the wax, but by that produced during its friction against the cap.

"This difficulty may, however, be avoided in most circumstances, simply by bringing the electrified non-conductor into contact with the cap, and retaining it there during the experiment; for the electricity which in this way is made by *induction* to exist in the leaves, and causes their divergence, is the same as that which would exist over the whole of the cap and leaves, if the electricity of the wax could be transferred to them.

"Such are the circumstances relating to the charge of the electrometer, by bodies brought into *contact* with it, and communicating to it part of the electricity they previously possessed. As before mentioned, when highly electrified, they cannot be so applied to the instrument without tearing the leaves to pieces; but they may then, when held at a distance, be made to diverge the leaves by *induction*, and even to communicate a charge to the instrument, and thus enable it to exhibit divergencies when the inducing electrified body is removed. The effects thus produced by induction are the same in kind, and nearly in extent, whether the electrified body be a mass of conducting or non-conducting matter, so that in this respect the metallic ball and the stick of wax are equal; the only difference being in the kind of electricity produced, which, with bodies charged positively, is the reverse of that occasioned by such as are charged negatively.

"When an electrified substance is placed at such a distance from the cap of the electrometer as to occasion considerable divergence, and is retained there for a few minutes, the divergence of the leaves will generally diminish, and the more rapidly as the instrument becomes cold or the glass damp, as the leaves are ragged, or any part of the cap angular and pointed.

"On removing gradually the electrified substance to such a distance that it can no longer affect the instrument, it will be found that the leaves will collapse at first, and afterwards expand again more or less, according as they had lost more or less of their first divergence.

"This ultimate divergence of the leaves will be due to a charge of electricity in the instrument, of the *opposite kind* to that of the inducing or approximated body.

"If no effect of this kind takes place, and there be no diminution of the first divergence, nor any ultimate change, then the insulation and goodness of the electrometer is proved by a powerful test. This being ascertained, then, if whilst the electrified body is in the neighbourhood, and the leaves diverged, the cap be touched by the hand, or any other conducting substance communicating with the earth, the divergence of the leaves will instantly cease. In this state of the instrument, if the communication be broken so as to leave the cap and leaves insulated, they will still remain collapsed; but if the inducing electrified body be now removed from the situation in which it at first caused the divergence, the leaves will immediately diverge, and the electrometer become charged with electricity of the *opposite* kind to that of the inducing body. The degree of charge thus given to the instrument will be in proportion to the degree of divergence induced in the leaves *before* they were made to collapse by the touch of the finger.

"In the case in which a weakly electrified non-conducting substance was directed to be laid on the cap of the electrometer, to occasion a divergence by electricity like its own, it may be observed that, if, during the experiment, the cap be touched by the fingers, and the electrified body afterwards removed, the leaves will first collapse, and then diverge with *opposite* electricity, although at the commencement of the experiment they were diverged with the *same* electricity as that of the body to be examined. If, therefore, the electricity of an excited body is to be examined, the leaves of the electrometer are in the first place to be diverged. This may be done with the *same* electricity, by bringing the body, if *weakly electrified*, into contact with the cap, leaving it there if of non-conducting matter, or removing it after contact if of conducting matter; or, if *strongly electrified*, by approaching it so near as to cause a sufficient divergence of the leaves, and retaining it there until the conclusion of the experiment. On other occasions however with strongly excited bodies, it may be convenient, either because of their size or other circumstances, to communicate a charge of the *opposite* kind, in the manner described; then upon determining what that kind is, in the manner to be immediately described, the electricity of the originally electrified body will of course be known to be opposite to it.

"The tests of the kind of electricity by which the leaves are diverged are of the following nature. A stick of sealing-wax rubbed with warm flannel becomes *negatively* electrified; a tube of warm glass rubbed with a dry silk handkerchief, or, better still, with a piece of silk having a little amalgam upon it, becomes *positively* electrified, both these excitations being so strong as to make the leaves of an uncharged electrometer diverge, whilst the wax or glass is at a considerable distance. If one of these excited substances be brought near the cap of an electrometer already diverged, it will either cause the divergence to increase or diminish. The divergence will *increase* if due to electricity of the *same* kind as that of the body approached, but will *diminish* if of the opposite kind; so that the electricity of the body approached being known, that of the electrometer will also be known, and consequently that of the excited body which had originally caused its divergence. The sealing-wax for instance is rendered *negative* by flannel; being approached to a diverged electrometer it may cause the leaves to collapse; the conclusion to be drawn is, that the electrometer leaves were in a *positive* state: being approached to another diverged electrometer it may increase the divergence, in which case it will indicate that the leaves of the electrometer were in a *negative* state. An excited rod of glass brought to these electrometers would make the first diverge still more, and would cause the second to collapse, in both cases indicating the same states as the wax.

"Some precaution is required with respect to the manner in which these excited rods are to be applied. The electrometer being diverged, the wax or glass is to be excited at such a distance as to have no influence over the instrument; the most strongly excited part of the wax or glass is then to be gradually approached to the cap, the hand and all other unnecessary conducting bodies being kept out of the way as much as possible, or at least not moved in the neighbourhood of the electrometer during the experiment. As soon as the rod begins to affect the leaves (even though the distance be two or three feet), the effect must be watched, and then their collapse or further divergence will become evident immediately on moving the rod a little way to or from the instrument.

"It is this first effect that indicates the kind of electricity in the electrometer, and not any stronger one; for although, if the repulsion be increased from the first, no approach will cause a collapse to take place except the actual discharge of the leaves against the sides of the glass, yet when collapse is the first effect, it may soon be completed, and repulsion afterwards occasioned from a too near approach of the strongly excited test-tube. It is, therefore, the first visible effect that occurs, as the test-rod is made to approach from a distance that indicates the nature of the electricity; and when this effect is observed, the rod should not be brought nearer, so as permanently to disturb the state of the electrometer, but should be removed to a distance, and again approached, for the purpose of repeating and verifying the preceding observation.

"It is to be understood, that the approach of the test-rod, though it affects the divergence, causes no permanent change of the electricity in the instrument, unless it be brought much too near, and cause considerable disturbance of the leaves. The electrometer will remain, after a good experiment, in the same state as at first.

"When the body to be examined is so strongly electrified that it may not be brought near to the electrometer, but has been placed at such a distance as to affect it, and left there to cause a proper divergence, then its place should not be directly over but rather on one side the cap, that the test-tube, when applied, may be brought towards the instrument on the other side; the originally electrified body, and the test-tube, being retained in directions as widely apart as they conveniently can be."

Saussure's Electrometer.

Saussure's electrometer. Plate CCXVI. Fig. 6, 7.

The electrometer by which Saussure made the observations on the electricity of the atmosphere is shown in fig. 6, 7. It consists of a glass vessel, ACB, of a bell shape, and so wide that the balls *g*, *g*, when at their maximum divergency, cannot reach the strips of tinfoil *h*, *h*, *h*, *h* pasted within the glass. The pith balls, which are spherical, should not be above half a line in diameter, and should be suspended by the finest silver wires, moving freely in nicely-rounded holes. Four pieces of tinfoil are used, each internal piece having a corresponding one on the outside; and the bottom of the instrument is made of metal, and round it there is a graduated scale for measuring the divergency of the balls.

In order to collect much electricity from the atmosphere, the instrument has a pointed wire one and a half or two feet long, which unscrews in three or four pieces; and in order to preserve its insulation, a small umbrella is screwed on the top of the instrument, see fig. 7. On other occasions he connected with a hook at H a fine metallic wire fifty or sixty feet long, at the end of which was a three or four ounce ball of lead, which he threw to the height of forty or fifty feet, in order to bring down the electricity of the atmosphere. Fig. 7.

By dividing between two equal and similar bodies the electricity contained in one, and carrying on the subdivision progressively downwards, M. Saussure determined the relation between the divergency of the balls *g*, *g*, and the force of the electricity which acted upon them. The results which he thus obtained are given in the following table.

Distance of Balls in fourths of a line.	Relative Forces of Electricity.	Distance of Balls in fourths of a line.	Relative Forces of Electricity.
1	1	13	23
2	2	14	26
3	3	15	29
4	4	16	32
5	5	17	36
6	6	18	40
7	8	19	44
8	10	20	48
9	12	21	52
10	14	22	56
11	17	23	60
12	20	24	64

Method using Sa sure's el trometer

In order to use this instrument, place it in open ground, free from trees and houses, and having screwed the conductor on the top of the electrometer, lay hold of it by its base, and place it so that the base and conductor may touch the ground at the same time; then raise it to the height of the eye, and observe on the scale the number of fourths of a line that the balls have diverged; then lower it till the balls almost touch each other, and measure the distance of the top of the conductor from the ground; this distance is the height at which the electricity of the air begins to become sensible. If the balls still diverge, the other parts of the conductor should be unscrewed, and it will then be seen at what height the electricity becomes sensible.

Hare's Single-Leaf Electrometer.

Hare's gle-leaf electron ter. CCXV Fig. 8.

As the divergency of the gold leaves is increased by the proximity of the strips of tinfoil, Dr Hare, of the university of Pennsylvania, conceives that the leaves are separated by attraction, and not by repulsion; and he was thus led to construct an electrometer with a single leaf, as shown in fig. 8. A brass ball one fourth of an inch in diameter is so situated that it may be made to touch the leaf, or retire from it to the distance of an inch, by means of a screw which supports it. It is obvious that this instrument is not only more simple than the double-leaved electrometer, but less liable to be destroyed by accident;

and Dr Hare informs us that it is exceedingly sensible, and that it has enabled him to detect the electricity produced by one contact between a copper and zinc disc, each six inches in diameter.

Henley's Quadrant Electrometer.

enley's adrant ctrome- . ate 'XVI. g. 9.

This useful instrument is represented in fig. 9. It consists of a semicircle of ivory, C, fixed to the side of a stand, AB, about seven inches high, rounded and smoothed in all its parts. The lower quadrant of the semicircle is divided into 90°, and a thin piece of cane, *ab*, is suspended at the centre *m* of the semicircle, carrying a pith ball, *b*. When the electricity to be measured is communicated to the instrument, the ball is repelled by the stem AB, and the angular elevation of the cane *ab* is a measure of the electrical force. This instrument may be screwed from its base B, and fixed on the end of the prime conductor, or on the summit of a Leyden phial. Mr Achard states from experiment that the quadrant should be divided according to a scale of arcs whose tangents are in arithmetical progression. It is most frequently used as an appendage to the prime conductor, for the purpose of measuring the state of action of the electrical machine.

In employing this instrument to show the progress of the charge of any jar or battery, Mr Faraday justly observes that it should be so placed that the moving index does not approach to any ball, wire, or surface charged similarly to itself, but on the contrary should recede from it. If it is therefore placed on the end of the conductor, the index should move outwards and away from the conductor, and not in a direction over it towards its more central parts; for the latter would interfere with the free indications of the electrometer, and in some cases would make it quite useless.

Brooke's Steelyard Electrometer.

ooke's elyard ctrome- . g. 10.

This electrometer, which is represented in fig. 10, is calculated to measure the number of grains which the repulsive force of the accumulated electricity is capable of raising. Its base AB, about nine inches and a quarter in diameter, adjusted horizontally by screws A, B, sustains an insulating pillar DD, upon which the electrometer rests. To the brass rod H are attached two tubes of copper, G, *g*, which have a motion round the rod, so as to be turned to a proper distance from the body whose electricity is to be measured. The tube G is screwed into a solid piece within the ball F, and moves in a vertical plane about an axis close to F. The balls I, K are of copper, and hollow. The arm E, which moves round an axis in a vertical plane behind the dial-plate R, carries a ball C, which touches the ball L fixed on the top of the glass rod DD. If the arm E rises from a vertical to a horizontal position, or through 90°, the index R on the dial is made to move through a whole circle, or 360°. The apparatus NPH forms the communication between the electrometer and the body whose electricity is to be measured.

Let the body be electrified positively, then the electrometer will be similarly electrified. The balls I, K will repel each other, G will rise in a vertical plane, L will repel C, and EC will also rise in a vertical plane.

The apparatus FG*g*IK is chiefly used for graduating the inner circle of the dial-plate. For this purpose a weight *m* moves along the rod G, till it forms an exact counterpoise to the weight of F. One end of the weight *m* will consequently be the *zero* of the scale. Let *m* be now shifted to *n*, near to the ball I, and determine by a pair of good scales the weight of the ball I, or rather the weight produced by shifting *m* to *n*. Divide the space *mn* into as many divisions as the grains now found, and subdivide it into halves and quarters. These divisions are now to be transferred to the inner circle of the dial-plate, by observing the position of the upper or shorter half of the index R when *m* stands at any number of grains in the scale *mn*. When the inner scale on the dial-plate is thus graduated, the arms G, *g* and balls I, K may be removed.

Cuthbertson's Balance Electrometer.

Cuthbertson's balance electrometer. Plate CCXVI. Fig. 11.

This electrometer, which is particularly useful for jars and batteries, is shown in fig. 11. It consists of a metallic rod CD, about thirteen inches long, terminated by balls C, D, and balanced on a knife edge, the ball *b* being constructed in such a manner as to permit the rod CD to move in a vertical plane. A bent tube of brass FG, supports a similar ball G; and four inches below D is placed another insulated ball E, which communicates with a wire and chain with the *outside* of the jar or battery. If the rod AB be now connected with the prime conductor, or the *inside* of the jar, and this last be electrified, the ball E will attract D, because they are oppositely electrified, from being connected with opposite surfaces of the jar; and when this attractive force exceeds the weight at *a* with which the opposite arm is loaded, the arm *b*D will descend and give out its electricity to the ball E. In order to obtain a measure of the attractive force between D and E, and consequently of the intensity of the charge, the arm C*b* is divided experimentally into sixty parts or grains, which are indicated by one side of the moveable index *a*. A Henley's quadrant electrometer is placed at A, to indicate the progress of the charge, which is not shown by the balance electrometer.

Mr Snow Harris's Electroscope.

Mr Snow Harris's electroscope.

This very ingenious and beautiful instrument, invented and used by Mr Snow Harris of Plymouth, to whom the science of electricity is under many obligations, is represented in fig. 12. The following description of it we owe to the kindness of the inventor:—

Fig. 12.

Fig. 12 represents an electroscope, which acts on the principle of electrical divergence. A small elliptical ring of metal, *a*, is attached obliquely to a small brass rod, *ab*, by the intervention of a short tube of brass at *a*; the rod *ab* terminates in a brass ball, *b*, and is insulated through the substance of the wooden ball *m*. Two arms of brass, *rr*, are fixed vertically in opposite directions on the extremities of the long diameter of the ring, and terminate in small balls; and in the direction of the shorter diameter within the ring there is a delicate axis at *a*, set on extremely fine points. This axis carries, by means of short vertical arms, two light reeds of straw, *an*, *an'*, terminating in balls of pith, and constituting a long index, corresponding in length to the fixed arms above mentioned. The index thus circumstanced is susceptible of an extremely minute force. Its tendency to the vertical position is regulated by small sliders of straw, *ss*, moveable with sufficient friction on either side of the axis. To mark the angular position of the index in any given case, there is a narrow graduated ring of card, board, or ivory, *ef*, placed behind it, the divisions being distinctly legible through sights cut in the reeds. This graduated circle is supported on a transverse rod of glass, *cd*, by the intervention of wooden caps, and is sustained by means of the brass ball *a*, in which the glass rod is fixed. The whole is supported on a long insulator of glass, A, by means of wooden caps terminating in spherical ends.

In the above arrangement, as is evident, the index will diverge from the fixed arms whenever an electrical charge is communicated to the ball *b*.

This instrument is occasionally placed out of the vertical position, at any required angle, by means of a joint at *m*; and all the insulating portions are carefully varnished with a solution of shell-lac in alcohol.

Mr Snow Harris's Electrometer.

Mr Snow Harris's electrometer. Plate CCXVI. Fig. 13.

The object of this electrometer, an account of which has been kindly communicated to us by its inventor, is to measure directly the attractive force of an electrified body, in terms of a known standard of weight, estimated in degrees on a graduated arch, *xy*, fig. 13. An insulated conductor, *f*, is fixed on a varnished rod of glass, *fg*, resting by the intervention of a wooden ball on the extremity of a micrometer screw, *s*, by the aid of which the conductor may be raised or depressed through given intervals to within the hundredth of an inch of any required point. A moveable and similar conductor, *m*, made of light wood, hollowed and gilded, is suspended immediately over the former from the periphery of a small brass wheel W, fig. 13 and 14, by means of a fine silver thread attached near its vertical arm, and passing from thence over its grooved circumference, as shown. This conductor, *m*, is counterpoised by a short cylinder of wood, *pn*, fig. 13, 14, suspended in a similar manner from the opposite side of the wheel by means of a silk thread, and resting partly in water contained in the glass vessel N, fig. 13.

The extremities of the axis of the wheel W, fig. 13, 14, are turned to extremely fine pivots, and rest on two large friction wheels, after the manner represented in the figures,[1] by which great freedom of motion is obtained.

There is a fine index of light straw, W*c*, attached to the extremity of a small steel needle, inserted diametrically through the circumference, which indicates on the graduated arc *xy* the force exerted between the conductors *m*, *f*. The weight of this index is accurately poised by a small globule of brass, *n*, fig. 14, moveable on a screw, cut in the opposite arm of the steel needle carrying the index.

The centre of the wheel W is accurately placed in the centre of the arc *xy*, which, with its radii of support, is made of varnished wood; the graduated scale being of card, board, or ivory. This arc is the sixth part of a circle, divided into 120 equal parts, 60 in the direction *cx*, and 60 in the direction *cy*; the centre *c* being marked zero.

Fig. 14.

Fig. 14 represents the wheel W, with the suspended conductor and counterpoise, the index and its balance-weight, together with the lines of suspension, passing freely over the circumference, and fixed at the point *ii*.

The various wheels above mentioned, with the graduated arc, are sustained on a projecting metallic rod, passing through a glass column B. The column is secured by means of the rod to a sort of double stand, *hh*, fig. 14, supported on three levelling screws. The interval between the plates of this stand contains the glass vessel N and the micrometer screw *s*. The upper plate has a circular hole, *p*, through which the cylindrical counterpoise passes into the water *n*. The levelling screws serve to regulate the position of the counterpoise through the hole; so that when it hangs in it centrally, the whole is accurately adjusted.

The gravity of the suspended conductor *m* being in the above arrangement opposed by that of the counterpoise, it may be so far considered as existing in free space devoid of weight, and will therefore become very readily moved by any new force applied to it. It may consequently be caused to approach to or recede from the fixed conductor *f*, by the operation of forces acting in either of these directions; the motion will, however, be speedily arrested by the cylindrical counterpoise *n*, which becoming either further immersed in, or otherwise raised in the water, furnishes, in the greater or less quantity of water displaced, a measure of the force. In this way the force may be estimated either in degrees or grains of actual weight; since the number of grains requisite to add to either side, in order to advance the index in either direction a given number of divisions, may be immediately found by experiment; and which, as the sections of the cylinder are all similar, will be found to increase or decrease with the degrees of the arc. Thus, if one grain advances the index in either direction five degrees, then two grains will advance it ten degrees, and so on.[2]

In the application of this instrument to electrical inquiries, the force to be measured is first communicated to the fixed conductor *f*, a free communication being established between the suspended conductor *m* and the ground, or otherwise with the negative side of the jar or battery, should the attractive force be derived from this species of accumulation; this is readily effected through the brass work of the apparatus, in connection with the rod passing through the interior of the glass column B.

For the repulsive force we connect the conductor *f* as before, and suspend *m* by a silk thread; in which case it will, after being electrified similarly to *f*, recede from it; but this method of experiment is evidently more complicated than the former, and liable to fallacy. The distance between the conductors *m*, *f* corresponding to a given force, is easily ascertained by means of the degrees indicated on the arc *x y*. In the instrument above described, each degree corresponds to a variation of distance between the conductors equal to the ·01 of an inch. If, therefore, at the commencement of any given experiment, we first bring the nearest points of the conductors *m*, *f* in contact, the index being in zero, and then depress the inferior conductor *f* a given distance, known by means of the micrometer screw *s*, then all subsequent distances may be readily determined between these points.

It is now only requisite to observe, that the interior of the cylindrical counterpoise is hollow, in order to weigh it accurately, and cause it to hang vertically in the water; and there is a small hemispherical cup, *p*, fixed on its stem for the reception of small adjusting weights, by which the position of the index at 0 of the scale is regulated with great nicety. With respect to the form of the conductors *m*, *f*, they are generally plain circular areas, backed by small cones, and are of about two inches diameter. Conductors of other forms, however, such as spheres and cylinders, may be occasionally used when the object is to experiment more particularly on bodies of peculiar forms.

Experiments with this instrument are remarkably clear, considering the subtile character of the principle we have to investigate. Thus, when the insulations are perfect, and the atmosphere dry, the index immediately exhibits the amount of the attractive force, and remains stationary for a much longer time than is required to note the result.

---

[1] Mr S. Harris resorted to this method of employing friction rollers, as being more efficient than that in which the axis is allowed to rest in the angle formed between the peripheries of four smaller wheels. In this case it rolls fairly on a large circumference, and is prevented from passing off it on either side by the check-wheels, either of which, when acted on, opposes little or no resistance to motion.

[2] The counterpoise should be free from grease or varnish of every sort, and should, previously to being used, be kept immersed in water: the insulation of the conductor *f* also should be made extremely dry, and occasionally warmed by a stick of burning charcoal.

By varying the superficial dimensions of insulated conductors, and the quantity of electricity accumulated on them, we may, by the help of the above instrument, deduce many curious and important laws of electrical action. It is, however, first requisite to explain a method of charging simple conductors with comparative quantities of electricity; for without an accurate measure of quantity, little can be effected in almost any department of this branch of science.

late CXVI. ig. 15. ig. A.

Simple conductors may have comparative quantities of electricity disposed on them, by abstracting small sparks from an insulated charged jar, fig. 15, either immediately on the given substance, or otherwise, on an insulated transfer plate, *p*, fig. A. An insulated jar charged with a given accumulation, as estimated by the unit of measure, which will be presently described, is of singular importance in researches with simple conductors; for series of sparks may be obtained from it of such slow convergence, that many successive terms may be considered as equal. Thus, an insulated metallic disc, *d*, being placed in connection with the electrometer, fig. 13, or with the electroscope, fig. 14, was electrified many times in succession to precisely the same amount, by sparks drawn on an insulated plate from the positive coating, the negative side of the jar after each contact being restored to a neutral state. When a portion of the charge was abstracted so as to sensibly decrease the quantity in the jar, then a new point is arrived at, from which another series of sparks can be obtained, differing extremely little in quantity; and this process may be continued to a low point of accumulation on the jar.

The quantity given off by the positive coating is dependent on the dimensions of the abstracting conductor, and on the free state of the negative side of the jar. If it be free for each experiment, or be otherwise connected with a conductor of sufficiently large dimensions, it may be observed that a conductor of a double capacity receives a double quantity, a conductor of a treble capacity a treble quantity, and so on. The extent to which this process may be carried with a jar exposing about two square feet of coating is somewhat considerable. We only require in these experiments an extremely perfect insulation.

In disposing given quantities of electricity on simple conductors in this way, and investigating the attractive force by means of the electrometer, Mr Harris arrived at the laws formerly explained. (See page 587.)

Lane's Discharging Electrometer.

Lane's discharging electrometer. Fig. 16.

This admirable instrument is shown in fig. 16. To the stem AB of a Leyden jar, MN, is fixed a bent piece of glass, BC, for the purpose of supporting and insulating the brass rod DE, which has two equal brass balls at its extremities. This rod moves through a spring tube at C, so that the brass ball D can be placed at different distances from the equal ball A, by which the jar is charged. The insulated ball D is connected through the metallic wire DE with the outside coating of the jar, by a wire, EF. If we bring the ball D near to A, a small electrical charge conveyed to the jar MN will discharge itself from A to D, and pass off to the ground by the wire EF. If the distance AD is increased, the jar must be more highly charged before it discharges itself; so that the distance AD of the balls is a measure of the intensity of the charge at the time of its discharge. As long therefore as the jar has not discharged itself, we are sure that its charge is less than that which corresponds to the distance AD. The chief defect of this instrument arises from the occasional interposition of particles of dust or other light conducting materials between the balls, which occasions the discharge to take place sooner than it otherwise would do. The arm of glass is sometimes fixed on the top of the charging rod, where a ball of wood is placed, and is bent downwards, so as to carry the balls D, E. In this case the jar is charged by another ball projecting from the charging rod towards D. This electrometer is sometimes fixed to the prime conductor, with and without a jar accompanying it.

Mr Snow Harris's Measuring Electrometer.

Mr Snow Harris's measuring electrometer.

This elegant instrument, which we have had the advantage of seeing in operation, is an invaluable addition to our electrical apparatus. According to the law of electrical accumulation on coated jars, the quantity added to one side is always proportional to the quantity given off by the other, and reciprocally. Hence the amount of the accumulation may be always estimated by insulating the jar to be charged, and observing, by means of a discharging electrometer, the explosions of a small jar connected with the negative coating. This process is, however, complicated in its general application; but Mr Harris has modified it in the following manner:—Let a small jar, N, be furnished with a discharging electrometer, *n*, and inverted as in fig. 17, being supported by a brass rod, *pq*, inserted into the ball D of the prime conductor ABC. Then, as the electricity passes up the rod and accumulates on the inner coating, a similar quantity is given off from the outer coating, which may be made to pass from a ball at *p*. Now when the small jar N has been charged to a given degree, an explosion or discharge takes place from *m* to *n*, and restores the equilibrium; and hence *one measure* of electricity is marked by the first explosion. When this has taken place, the jar is in the same state as at first; and hence by a repetition of the process we obtain the exact number of measures (or explosions) which pass from the unit jar N, and are finally accumulated on the jar J, or battery, into which the electricity passes from the ball *p*. This process of charging a battery from the outer coating of an exploding jar, instead of from the prime conductor, supersedes all electrometers, and is the best way of measuring quantity.

Plate CCXVI. Fig. 17.

Volta's Flame Electrometer.

Volta's flame electrometer.

It was observed by Mr Bennet, that a lighted candle placed above the cap of his electrometer, and communicating with it, greatly increased the sensibility of the instrument; and it appears from various experiments that flame possesses the property of carrying off from bodies the electricity with which they are charged. M. Volta ingeniously availed himself of this principle in order to bring down to his electrometer the electricity of the atmosphere, the nature and intensity of which he was desirous of examining. This effect is produced by elevating above the atmospherical conductor a lighted match or torch.

Matteucci's Phosphorus Electrometer.

Matteucci's phosphorus electrometer.

As the preceding instrument cannot be employed when there is the least wind or rain, and still less during a storm of hail or wind, M. Matteucci conceived the idea of constructing an electrometer depending on the strong conducting power of the vapour of phosphorus. He prepared rods of this substance between the twenty-fifth and the fiftieth of an inch in diameter, by melting the phosphorus under water, and by blowing it while in a state of fusion through a tube of the requisite diameter. He afterwards made the rod of phosphorus project from the fiftieth to the seventy-fifth of an inch beyond the end of the tube. He then fixed the glass tube on a wooden pole, and he insulated the pole by fixing to its extremity a glass handle. The phosphorus communicated by its base with a metallic wire which descended along the pole, and which could be kept at a distance from the pole by some tubes of glass placed at regular distances. M. Matteucci kept the rod of phosphorus perfectly insulated in the time of rain, by means of a glass hood varnished on both its surfaces, and having its convexity turned upwards. The pole was composed of three or four rods, which were adjusted into one another; and the instrument thus constructed was found extremely useful in examining the electricity of the atmosphere.

Mr Ronalds' Improvements on Electrometers.

Ronalds' improvements on electrometers. Plate CCXVI. Fig. 18.

As threads, pith or cork balls, and even straws when very dry, lose some of their conducting power, Mr Ronalds prefers fine silver wire, and hard charcoal balls from boxwood, for electrometric purposes. The following is the method which he employs in making electrometers of this kind. The instrument which he uses is represented in fig. 18, where ABCD is a bow of steel wire with a hook at each end. When the charcoal ball has been threaded on the silver wire, and rings formed at each end, it is *very* gently stretched in this bow, by passing the hooks through the rings, and shoving it forward with the thumb placed against the end of the tongue near the handle, which tongue is thus made to open wider by pressing the screw E on each side. The screw E is then turned a little farther into the piece F, in order to fix it firmly. The fine wire is now placed cautiously upon a piece of iron, a little below a red heat, which will make it perfectly straight, when it may be taken from the bow, and suspended on one of the rings of the piece of brass, fig. 19. In fig. 20 is shown Mr Ronalds' method of making gold-leaf electrometers.

Fig. 19, 20.

The electroscopes of the Abbé Haüy, and the torsion electrometer of Coulomb, have been described in a preceding part of this treatise.

CHAP. IV.—ON MISCELLANEOUS ELECTRICAL INSTRUMENTS.

1. *Mr Snow Harris's Electrical Balance.*

Mr Snow Harris's electrical balance. Plate CCXVII. Fig. 1.

In investigating the law of the attractive forces of electricity accumulated in jars and batteries, Mr Harris made use of the electrical balance shown in fig. 1. The beam *mn* of the balance, constructed in the usual manner, is suspended from a projecting arm of brass, *ea*, supported by a vertical stand, *abc*, consisting of a brass slider and socket, *ab*, by which the balance can be moved up or down, and of a glass tube, *bc*, with a ball of varnished wood, *b*. A wire, pointed out by the line *ef*, passes through the tube *abc*, and connects the beam with the *negative* coating of the jar. A hollow gilt conductor of wood, *f*, is suspended by a metallic thread from one of the arms *m*, and from the opposite arm *n* is hung by silk lines a light brass scale, *d*. In this scale there is placed as much additional weight as will balance the conductor *f*, and put the whole in a state of equilibrium. By means of an insulated conductor f', of the same dimensions as *f*, and fixed directly under it, the attractive force of the electricity in the jar is made to act directly on the suspended conductor *f*. The conductor f', which is connected with the positive coating, is so placed that it can be depressed from contact with the conductor *f*, through given distances, by means of a cylindrical slide, *r*, attached to it, which moves in the socket *s*, and indicates its depression on an engraven scale, divided into twentieths of an inch. The socket *s* is supported on a glass pillar by means of a varnished ball of baked wood, on which the socket is fixed, and through which the conductor f' is connected with the positive coating. The whole balance can be raised or depressed through a small distance by the micrometer screw at *e*.

From this description it is obvious that the attractive force acts directly between the conductors *f* and f', and can therefore be measured by weights placed in the scale *d*. The scale rests on a small circular stand *q*, which can be raised or depressed by the sliding brass rod and tube *vt*, to accommodate itself to the horizontal position of the beam, and to check any oscillation. The balance is fixed on an elliptical base, having three levelling screws.

The following experiment, made by Mr Harris, will best explain the use and value of this balance.

Having connected the inside coating of a single jar containing five square feet with the conductor *f*, and the outside coating with the wire *ac*, the conductor f' was depressed through half an inch, and a weight of sixteen grains was placed in the scale; then, when five turns of the plate were completed (or, if the measuring electrometer is used, when *n* explosions were conveyed to the jar), the attractive force between *f* and f' was sufficient to tip the beam. The accumulated electricity being discharged, the conductor f' was depressed through a *second interval of half an inch*, making the whole distance *one inch;* and *four grains* or one fourth of the former weight being placed in the balance, the beam was again depressed with *five* turns of the plate, or *n* explosions of the measuring electrometer. The accumulation being again discharged, and the conductor *f* depressed through a third interval of half an inch, and one ninth part of the first weight placed in the scale, the beam was again depressed with five turns of the plate, or *n* explosions. Hence, as the distances in the first experiment were as two to one and the weights four to one, and as in the second experiment the distances were three to one and the weights nine to one, we may infer *that the attractive force between the conductors varied in the inverse ratio of the square of their distance.*

2. *Dr Ure's Detonating Eudiometer.*

Dr Ure's detonating eudiometer. Plate CCXVII. Fig. 2.

The electrical eudiometer is a simple instrument, for detonating or exploding gases by means of an electrical spark or shock. The common eudiometer is merely a short tube of glass closed at the upper end, and having two pieces of platina wire passing through the glass near its upper end, so as nearly to meet at the axis of the tube. These wires communicate, the one with the inner and the other with the outer coating of a charged jar, so that when the discharge passes between the platina points, it inflames the gas in the tube. As the gas subjected to the action of the spark is transferred to the tube over water or mercury, the lower or open extremity of the eudiometer must be kept in the water or mercury, in order to confine the gas. With the common eudiometer two persons are required, the one to manage the instrument and the other to manage the electrical machine; but Dr Ure has given it such a form that a single individual can perform all the operations with the greatest facility.

Fig. 2.

Dr Ure's instrument, shown in fig. 2, consists of a glass syphon, ABC, with a bore of from two tenths to four tenths of an inch. Its legs AB, CB are from six to nine inches long, and from one fourth to half an inch apart. The open end A is slightly funnel-shaped, and the other, C, which is hermetically sealed, has two platina wires, *a*, *b*, inserted near it by the blowpipe. The outer end of the one wire is bent vertically upwards, and then horizontally so as nearly to touch the edge of the aperture A. The end of the other wire is formed into a little hook, to allow a small spherical button, *d*, to be attached to it when the electrical spark is to be transmitted. The sealed leg CB is graduated by introducing in succession equal weights of mercury from a measure glass tube. Seven ounces Troy and sixty-six grains occupy the space of a cubic inch, and thirty-four and a half grains represent a hundredth part of that volume.

Plate CCXVII. Fig. 3.

The method of using this apparatus is shown in fig. 3. The whole syphon being filled with mercury or water, a convenient quantity of the gas to be examined, not exceeding one sixth of the capacity of the tube, must then be introduced in the ordinary manner. The tube is then held upright by the hand, and the gas being transferred into the sealed leg CB, the mercury is brought to a level in both legs, either by the addition of a few drops, or by displacing a portion by pushing down a glass or wooden rod. The tube being grasped as in the figure, the thumb must be placed tightly over the aperture, so as to close it, and at the same time touch the wire next it. A spark from the conductor of the electrical machine is then made to enter the button d, and after inflaming the gas, is conducted away by the thumb and hand of the operator, the tip of the finger feeling only a slight push or pressure. When two or more inches of air are left beneath the thumb, it acts as a recoil spring to restrain the violence of the explosion. When condensation of volume takes place, the finger feels pressed down to the orifice. On sliding it gradually to one side and admitting the air, the mercurial column in CB will rise above that in AB. More mercury must then be poured in till the equilibrium is restored, when without any reduction we may read off the resulting volume of gas. If the charge of a jar is to be transmitted through the wires, the thumb must not touch the wire when it closes the aperture. In this case the wire from the outside coating must be hooked on the eudiometer wire nearest the thumb, and then the knob or ball on the charging rod of the jar must be brought in contact with the button on the other wire, when the gas will be exploded.

3. *Volta's Electrical Lamp.*

olta's ectrical mp.

As hydrogen gas is readily inflamed by a very small electrical spark, Volta conceived the idea of constructing a lamp for temporary purposes, such as that of obtaining a light at night, or in summer for the purpose of sealing letters, by employing the electrophorus to light the hydrogen. With this view a quantity of gas is put into a reservoir, and when subjected to the pressure of a column of water, it escapes from a small aperture by turning a stop-cock. Beneath this reservoir is placed an electrophorus in a box, and from the upper part of the box a wire passes through a glass tube to the small aperture. When the handle of the stop-cock is opened to let out the gas, the cover of the electrophorus is raised by means of a silk cord connected with the handle of the stop-cock, and the spark from this cover is conveyed by this insulated wire to the stream of gas, which is instantly kindled, so as to allow a candle to be immediately lighted. From the smallness of the quantity of gas consumed, a light may be procured an hundred times from the same reservoir of gas. When the hydrogen gas is expended, it is troublesome to persons unaccustomed to chemical manipulations to replenish the reservoir with fresh gas. M. Gay Lussac removed this defect by suspending a bar of zinc on the apparatus, so as to reproduce, by the action of diluted sulphuric acid[1] upon it, as much gas as was exhausted.

r Cut- sh's im- vement on it.

Although a good electrophorus, when well excited, will retain its charge for many months, yet in general its operation has been so uncertain, especially in damp weather, that many persons have been obliged to lay aside the instrument. Mr Cutbush of Philadelphia found that he could produce a spark in the dampest weather when he warmed the electrophorus before exciting it with a fox's tail, and kept the electrophorus box as tight as possible. As the cock is apt to become loose and allow the gas to escape, Mr Cutbush applied a mixture of tallow and finely pulverized plumbago to the cock; and, what is very curious, he found that the hydrogen gas prepared from zinc escapes much more readily than that procured from iron filings. He found that the former sometimes disappeared in twenty-four hours, while the latter often remained more than a week. The gas from iron filings is more impure than the other, from containing more or less carbon. With these precautions Mr Cutbush found that the lamp of Volta seldom disappointed him in producing flame. He ascertained that one cubic inch of gas will light the taper at least ten times if the cock is quickly turned.

Green's hydrogen lamp.

A hydrogen lamp acting by Voltaic electricity in place of that of the electrophorus has been invented by Professor Jacob Green of Nassau Hall, and is quite independent of the state of the atmosphere. Its description, however, belongs to the subject of another article.

4. *Ronalds' Electrograph.*

Ronalds' electrograph. Plate CCXVII. Fig. 4.

M. Magellan had proposed to delineate the changes which take place in the electricity of the atmosphere, by a cylindrical and a plain electrograph. As our limits, however, will not permit us to describe these instruments, we shall content ourselves with giving a drawing and description of the more recent and useful electrograph invented by Mr Ronalds. This instrument is shown in fig. 4, where AA is a box with a strong time-piece placed horizontally, and moved by the weight B, and CC a disc of baked mahogany eight inches in diameter, with an aperture of 2½ inches at D. The circumference of this disc, and also that of the perforation, are provided with edges or rims, and the outer broad rim is divided off and marked with hours and minutes like a common clock. The space between the two edges is almost filled with cement, composed of rosin, bees' wax, and lamp-black, and this part of the apparatus may be taken from the box at pleasure. A glass tube EF, with brass caps, and covered inside and out with hard cement, screws by its lower end into the disc CC, while the upper end carries a small sheave, g. Within this tube EF a stem of glass is fixed by its lower end on the minute arbor of the time-piece, and a pivot attached to its upper extremity passes through F and the sheave g. This pivot carries the iron ball and cap h, into which is screwed the horizontal steel wire i, carrying the slider k, which moves with little friction along the wire. The piece k carries the vertical wire l, terminating below in a hook, upon which hook is hung a ring at one end of a short wire m, whose other end carries a small gold bead. A fine thread, n, is attached to k by one end, and by the other to the sheave g.

When the clock is going, its minute arbor carries round the arm k, and the effect of this is to coil the thread n round the fixed sheave g, and to make the piece k advance towards the ball h, so that the gold bead will trail upon the resinous disc CC, and describe a spiral upon it. If we now cause the little iron cap above h to communicate with a wire connected with any atmospherical conductor, the gold bead will electrify the resinous surface, so that when the plate is removed from the clock and powdered with pounded resin, or even dry hair powder, the spiral line will exhibit configurations varying in shape and in breadth according to the intensity and nature of the electri-

---

[1] The acid should be diluted in the proportion of one part of acid to seven of water.

Electrical Apparatus.

city which the resinous surface has received from the trailing bead. The times at which these phenomena took place will be shown by the dial-plate.

If this instrument is used for recording the phenomena of serene weather, dew, &c. the hour arbor should be used in place of the minute one; but if for those of a thunder storm, hard shower of rain, or hail or snow, the minute arbor should be used. Mr Ronalds adds, that he has sometimes found a more rapid motion necessary, which can be obtained by the addition of a third arbor; the glass tube EF, with its appendages, being transferred to the most suitable arbor, and the disc adjusted to a new centre. Sheaves larger and smaller than *g* will be requisite for different applications of this electrograph.

5. *The Electrical Air Thermometer.*

Kinnersley's electrical air thermometer. Plate CCXVII. Fig. 5.

This instrument, invented by Mr Kinnersley, is shown in fig. 5, where AB is a glass tube about ten inches long and two inches wide, having its ends closed by two air-tight brass caps, A and B. Through these caps slide two hooked wires, FG, EI, so that the small brass balls G, I, can be set at any distance, and an electrical spark passing between them may be made stronger or weaker as the occasion requires. Another small tube, HA, open at both ends, passes through a tube in the copper caps, and through this tube a sufficient quantity of mercury or water is introduced to fill the lower ends both of the wide tube AB and the narrow one HA. If an electrical charge is sent through the balls G, I when they are placed in contact, by connecting the hooks E, F with the outside and inside coating of a Leyden jar, no effect will be produced; but if the balls G, I are separated so that the charge passes in the form of a spark through the interposed air, the rarefied and displaced air will press on the surface of the mercury or water at the bottom of the tube AB, and raise it nearly to the top of the small tube HA. It will then sink after the explosion, and resume its former position.

6. *Volta's Electrical Pistol.*

Volta's electrical pistol.

A brass vessel of a pear shape, or of an ellipsoidal form, being perforated at its two ends, a glass tube of the same diameter as the perforation is inserted in one of them, so as to extend to the centre of the ellipsoid, and to project about four inches beyond the vertex. Through this tube there passes a metallic stem, which is furnished with a brass ball at its outer end, while its other extremity reaches beyond the inner end of the glass tube. A mixture of equal parts of hydrogen gas and atmospheric air having been introduced at the second aperture, this aperture is closed tightly with a cork. The operator now grasps the ellipsoid by its equator, and when a spark is taken by its brass ball from the prime conductor, the gaseous mixture will instantly be exploded, and drive out the cork with a smart explosion. In place of a mere perforation at the extremity of the ellipsoid, a barrel may be inserted, and by using a cylinder of cork as a wadding, a ball may be discharged from the pistol.

Fig. 6.

Another form of the electrical pistol is shown in fig. 9, at BCF, forming a part of Mr Ronalds' electrical telegraph. The pistol has the form of a pear, and the brass rod and ball, in place of being a continuation of its axis, is inserted on one side, as shown at D. We have given a separate section of this pistol in fig. 6, where AB is the body of the pistol, which contains the inflammable gas, C the cork which is to be discharged, D the glass tube, G the brass ball with a brass rod going down through the glass tube and extended a little beyond it, and E another little ball and rod fixed in the lower end of the pistol. When the spark is communicated at G, the gas will explode and discharge the cork.

7. *Ronalds' Electric Telegraph.*

Electrical Apparatus.

Ronalds' electric telegraph.

M. Cavallo suggested the idea of conveying intelligence by passing given numbers of sparks through an insulated wire in given spaces of time; and some German and American authors have proposed to construct galvanic telegraphs by the decomposition of water. Mr Ronalds, who has devoted much time to the consideration of this form of the telegraph, proposes to employ common electricity to convey intelligence along insulated and buried wires; and he proved the practicability of such a scheme by insulating eight miles of wire on his lawn at Hammersmith. In this case the wire was insulated in the air by silk strings; but he also made the trial with 525 feet of buried wire. With this view he dug a trench four feet deep, in which he laid a trough of wood two inches square, well lined both within and without with pitch, and within this trough were placed thick glass tubes, through which the wire ran. The junction of the glass tubes was surrounded with short and wider tubes of glass, the ends of which were sealed up with soft wax.

Plate CCXVII. Fig. 7.

Mr Ronalds now fixed a circular brass plate, fig. 7, upon the seconds arbor of a clock which beat dead seconds. This plate was divided into twenty equal parts, each division being worked by a figure, a letter, and a preparatory sign. The figures were divided into two series of the units, and the letters were arranged alphabetically, omitting J, Q, U, W, X, and Z. In front of this was fixed another brass plate, as shown in fig. 8, which could be occasionally turned round by the hand, and which had an aperture like that shown in the figure, which would just exhibit one of the figures, letters, and preparatory signs, for example 9, V, and Ready. In front of this plate was suspended a pith ball electrometer, B (see fig. 9) from a wire, C, which was insulated, and which communicated on one side with a glass cylinder machine, D, and on the other side with the buried wire. At the further end of the buried wire was an apparatus exactly the same as the one now described, and the clocks were adjusted to as perfect synchronism as possible.

Fig. 8.

Fig. 9.

Hence it is manifest, that when the wire was *charged* by the machine at either end, the electrometers at both ends *diverged*, and when it was *discharged* they collapsed, at the same instant. Consequently, if it was discharged at the moment when a given letter, figure, and sign, on the lower plate, fig. 7, appeared through the aperture, fig. 8, the same figure, letter, and sign would appear also at the other clock; so that by means of such discharges at one station, and by marking down the letters, figures, and signs seen at the other, any required words could be spelt.

This is not the place to describe the method of using the telegraphic dictionary, but we may state, that the electrical pistol F, which passed through the side of the clock-case GG, had an apparatus H, by which a spark might pass through it when the sign *prepare* was made, in order that the explosion might excite the attention of the superintendent, and obviate the necessity of close watching.

8. *Ronalds' Atmospherical Conductor, founded on a New Mode of Insulation.*

Ronalds' atmospherical conductor. Fig. 10.

This conductor is shown in fig. 10. A glass pillar, A, passes through a circular piece of hard boxwood, B, and also through the piece C, the sides of the perforations in these pieces being lined with thick leather. Nut bolts, D, D, pass through B and C, to secure the glass pillar in its place. The dotted part of the support is hollow. The glass is about one fourth of an inch thick at the opening, and the upper part of it is coated with sealing-wax. A small spirit-lamp, E, with a single thread of cotton wick, and having a glass chimney, is placed beneath the open mouth of the glass pillar. The pillar terminates above with a strong brass socket carrying the ball F, which is perforated to admit the lowest joint of a long bamboo fishing-rod G, gilt and inclined at an angle of about 45°. The strong bent wire H carries the upper part of a Volta's straw electrometer I, which rests upon the table M. The piece which supports the straws is entirely detached from the glass bottle I, being fixed to the arm H when the instrument is in use. The same piece carries a cone or funnel K. From the bent wire N, similar to H, a pair of wood charcoal balls are suspended, or instead of them the quadrant electrometer O, which serves to mark the higher electrical intensities, such as those of rain, hail, snow, and heavy clouds, which are too strong to be measured by more delicate instruments.

When this instrument is screwed upon a table in an upper room, and the fishing-rod thrust out of the window, it will be found highly useful for examining the usual atmospherical electricity of serene weather. If it is to be used in the open air the ball F is unnecessary, and the rod can be placed vertically in the brass socket. Two insulators of this kind may be used to sustain a wire if required. (N. N. N.)

ELECTRIDES, anciently islands in the Adriatic Sea, which received their name from the quantity of amber (*electrum*) which they produced. They were at the mouth of the Po, according to Apollonius of Rhodes; but some historians doubt their existence.

ELECTRO-MAGNETISM. See Galvanism, Magneto-Electricity, and Thermo-Electricity.

ELECTROMETER. See Electricity.

ELECTUARY, in *Pharmacy*, a form of medicine composed of powders and other ingredients, incorporated with some conserve, honey, or syrup, and divided into doses, like boluses.

Vossius observes, that all the remedies prescribed for the sick, as well as the confections taken by way of regale, were called by the Greeks *εκλειγματα*, from the verb *λειχω*, *I lick;* whence, he thinks, was formed the Latin *electarium*, and afterwards *electuarium*. This conjecture he supports from the laws of Sicily, where it is ordained that *electuaries*, syrups, and other remedies, shall be prepared after the legal manner. The Bollandists, who relate this etymology, seem to confirm it.

ELEEMOSYNA Carucarum, or *pro Aratris*, in our ancient customs, a penny which King Ethelred ordered to be paid for every plough in England, towards the support of the poor. Sometimes it is also called *eleemosyna regis*, because first appointed by the king

ELEEMOSYNARIUS, in our old writers, means the almoner or peculiar officer who received the eleemosynary rents and gifts, and distributed them for pious and charitable purposes. There was an officer of this description in all religious houses. Formerly the bishops also had their almoners, as the king has at present.

ELEGANCE (from *eligo*, I choose), denotes a manner of doing or saying any thing politely, agreeably, and choicely; politely, so as to please people of delicate taste; agreeably, so as to diffuse a relish which gratifies every body; and choicely, so as to rise above the common way or mode.

ELEGIT, in *Law*, a writ of execution, which lies for a person who has recovered debt or damages; or upon a recognizance in any court against a defendant who is not able to satisfy the same in his goods.

ELEGY, a plaintive poem, written in a kind of stanza or verse the cadence of which is suited to the expression of mournful feelings and sentiments.

ELEMENT, in a figurative sense, is used for the principles and foundations of any art or science; as Euclid's Elements.

Elements, in *Physics*, the first principles of which all bodies are composed. These, it has been supposed, are few in number, unchangeable in their nature, and, by their multiform combinations, produce that endless variety of objects which we observe in the works of creation.

Elements, in *Astronomy*, are those principles deduced from astronomical observations and calculations, and those fundamental numbers which are employed in the construction of tables of the planetary motions. Thus, the elements of the theory of the sun, or rather of the earth, are his mean motion and eccentricity, and the motion of the aphelia. The elements of the theory of the moon are its mean motion, that of its node and apogee, its eccentricity, the inclination of its orbit to the plane of the ecliptic, and so on.

ELENCHUS, in *Antiquity*, a kind of ear-ring set with large pearls.

Elenchus, in *Logic*, by the Latins called *argumentum* and *inquisitio*, is a vicious or fallacious argument, which deceives under the appearance of a truth, and is the same with what is otherwise called *sophism*.

ELEPHANT. See Mammalia.

Knights of the Elephant, an order of knighthood in Denmark, conferred upon none but persons of the first rank and merit. It is also called the *order of St Mary*. Its institution is said to have arisen from a gentleman belonging to the Danish crusaders having killed an elephant in an expedition against the Saracens in 1184; in memory of which achievement King Canute instituted the order. The badge is a towered elephant, with an image of the holy virgin encircled with rays and suspended by a watered sky-coloured ribbon, like the George in England.

ELEPHANT ISLE, called by the natives Gharipoor, a small island situated between Bombay and the main land, about five miles and a half from Bombay. It is nearly five miles in circumference, and contains about a hundred inhabitants, who are employed in the cultivation of rice, and in rearing sheep and poultry for the Bombay market. The island is nearly overgrown with wood of a luxuriant growth, and contains several springs of good water. But it owes its chief celebrity to the mythological excavations and sculptures of Hindu superstition which are contained in it. Opposite to the landing place is a colossal statue of an elephant, cracked and mutilated, from which the Portuguese gave the island the name which it still bears. At a short distance from this is a cave, the entrance to which is nearly sixty feet wide and eighteen feet high, supported by pillars cut out of the rock; the sides are sculptured into numerous compartments containing various representations of the Hindu deities, but the figures have many of them been defaced by the blind zeal of the Mahommedans and Portuguese. In the centre of the excavations there is a remarkable bust of the Hindu Triad, or three-formed god, namely, Brahma the Creator, Vishnu the Preserver, and Seva or Mahadeva the Destroyer. The heads are six feet in length, well cut, and the countenances, with the exception of the under lip, are handsome. The head-dresses are curiously ornamented; and one of the figures, that of the destroyer, holds in its hand a cobra capella snake, whilst on the cap are, amongst other symbols, a human skull and a young infant. On each side of the Trimurti is a pilaster, the front of which is filled up by a human figure leaning on a dwarf, both much defaced. There is a huge compartment to the right, hollowed a little, and covered with a great variety of figures, the largest of which is sixteen feet high, representing the double figure of Seva and Parvati, named Viraj, half male and half female. On the right is Brahma, four-faced, on a lotus; and on the left is Vishnu. On the other side of the Trimurti is another compartment with various figures of Seva and Parvati, the most remarkable of which is Seva in his vindictive character, eight-handed, with a chaplet of skulls round his neck. On the right of the entrance of the cave is a square apartment, supported by eight colossal figures, containing a gigantic symbol of Mahadeva or Seva cut out of the rock. There is a similar chamber in a smaller cavern, having the walls covered with sculptures, which however can hardly be seen, owing to the rubbish with which the place is filled. This singular seat of Hindu superstition is said to have been dedicated to Seva, but it contains numerous representations of all the Hindu deities. It has, however, from time immemorial been forsaken by its priests or Brahmins; and it is not even the resort of pilgrims; its only devotees being married women, who offer up their prayers here for an increase of their family. This place is a most wonderful monument of antiquity and superstition. The work must have been one of incredible labour; and there is not the least trace or tradition to point out the time when this temple flourished, much less the period of its formation. Yet it clearly shows that the Brahminical religion must have flourished in India at a very remote period of antiquity. Long. 73. E. Lat. 18. 57. N.

ELEPHANTIASIS, called also the *leprosy of the Arabians*, in *Medicine*, a chronical disease, one of the two species of leprosy which affects the whole body, where even the bones as well as the skin are covered with spots and tumours, which are at first red, but ultimately become black.

ELEPHANTINE, a small island of the river Nile, now *Geziret-el-Zahir*, or the Flowery Island, distant half a stadium from Syene in Upper Egypt. The beauty of nature in this confined spot formed a strange contrast to the arid appearance of the country along the banks of the Nile. The inhabitants protected it against the inundations of the river by powerful dykes; and when the heats of summer had parched up every other part of the land, here nature appeared in all the verdure of spring, by means of artificial irrigation. This island being only one hour distant from the Cataract, became naturally the emporium of all the trade which was carried on with the inhabitants of the more southern portions of Africa. There was a city in it, of the same name, which contained a temple of Knuphis, and a nilometer, which is thus described by Strabo (xvii. 817): "The nilometer is a well or cistern on the banks of the Nile, built of well cemented stone (συννόμῳ λιθῳ). It serves to mark the height of the inundation, as the water in this well rises and falls with that of the river: there are marks on the wall which show the height of the increase, and the result of this observation is regularly published for the use of the cultivators of the ground. By this means they are able to judge to what height the inundation will rise, and thereby the labourers are enabled to regulate the proper distribution of the water. The governors of the province also regulate by this the tax imposed upon the land, for they increase it in proportion as there is an appearance of the water rising to a great height." It is curious that neither this intelligent geographer nor any of the ancient writers have thought proper to inform us how high the Nile rose when confined within precipitous banks, as it was in this southern portion of the country. It is from Aristides, who lived in the second century, that we first learn that it rose twenty-eight cubits above the lowest water mark; yet this was not sufficient to cover the valley with water, and it is now an arid desert, incapable of cultivation. See article EGYPT.

ELEPHANTINE, in Roman antiquity, an appellation given to the books in which were registered the transactions of the senate and magistrates of Rome, the emperors, or the generals of armies, and even of the provincial magistrates, the births and classes of the people, and other things relating to the census. They are supposed to have been so called, from having been made of leaves of ivory or elephants' tusks.

ELEUSINIA, in Grecian antiquity, a festival observed in honour of Ceres, by some states every fourth, but by others every fifth year. The Athenians celebrated it at Eleusis, a town of Attica; and hence arose the name.

Ceres, says Isocrates, wandering in quest of her daughter Proserpine, arrived in Attica, where some good offices were rendered her, which it is unlawful for those who are not initiated to hear. In return she conferred two unparalleled benefits, namely, the knowledge of agriculture, by which the human race is raised above the brute creation; and the mysteries, from which the partakers derive sweeter hopes than other men enjoy, both as to the present life and a future state of existence. It was the popular opinion that the Eleusinian goddesses suggested prudent counsel to their votaries, and influenced their conduct; and that the latter were respected in the infernal regions, and had precedence in the assemblies of the blessed, whilst the unhallowed were left in utter darkness, wallowing in mire, or labouring to fill a leaky vessel. The Athenians were solicitous to secure these advantages to their children, by having them initiated as soon as possible in the Eleusinian mysteries.

Ceres was supposed to be particularly partial to Eleusis and its vicinity. There were the memorials of her presence and of her bounty; the well named *Callichorus*, by which she had rested, in the reign of Erectheus; the stone on which she sat, named the *sorrowful;* the Rharian plain, where barley was first sown; and the thrashing floor and altar of Triptolemus, a herdsman whom she instructed in the culture of that grain, the use of which succeeded to acorns. Her mysteries continued to possess a pre-eminence in holiness, and to be accounted as much superior to all other religious festivals as the gods were to the deified heroes. Even the garments worn at the solemnity were supposed to partake of the efficacy of the mysteries, and to be possessed of signal virtues. It was customary to retain them until they began to decay, and then to dedicate them in the temple, or to use them as swaddling clothes.

The mystic temple, as it was called, provided by Pericles for the solemnity, created by its sanctity an awe only equalled by the astonishment which its beauty and magnitude excited in every beholder. The profane or uninitiated were forbidden to enter it upon any pretence. Two young Acarnanians happening inadvertently to mix with the crowd at the season of the mysteries, and to go in, were discovered and put to death. The chief priest, hierophant, or mystagogue, was taken from the Eumolpidæ, a holy family which flourished at Athens, and derived its descent from Eumolpus, a shepherd and favourite of Ceres. He was enjoined to observe celibacy, and he wore a stole or long garment, and in his hair a wreath of myrtle. The grand requisites in his character were strength and melody of voice, solemnity of deportment, magnificence, and strict decorum. Under him, besides many of inferior station, was the daduchus or torch-bearer, who likewise wore his hair with a fillet; the priest, who officiated at the altar; and the hiero-ceryx, or sacred herald; all very important personages. The latter was of a family which claimed the god Mercury, and Aglauros, the daughter of Cecrops, for its ancestors.

The secrecy in which the mysteries were enveloped served to enhance the idea of their consequence, and to increase the desire of participation. It was so strict that no person was allowed even to name the hierophant by whom he had been initiated; whilst public abhorrence and detestation awaited the babbler, and the law decreed that he should die the death.

The Athenians suffered none to be initiated into these mysteries excepting such as were members of their city. This regulation, which compelled Hercules, Castor, and Pollux, to become citizens of Athens, was strictly observed in the first ages of the institution; but after a time all persons, barbarians excepted, were freely admitted.

The festivals were divided into greater and lesser mysteries. The institution of the latter arose out of the following circumstance. Hercules having passed near Eleusis while the Athenians were celebrating the mysteries, desired to be initiated. As this request could not be complied with, he being a stranger, and as Eumolpus was unwilling to displease him on account of his great power, and the services which he had rendered to the Athenians, another festival was instituted without violating the laws; it was denominated *μικρα*, and Hercules was solemnly admitted to the celebration, and initiated. These lesser mysteries were observed at Agræ, near the Ilissus. The greater were celebrated at Eleusis, from which place Ceres has been called *Eleusinia.* In later times the lesser festivals were preparatory to the greater, and no person could be initiated at Eleusis without a previous purification at Agræ. This purification they performed by keeping themselves pure, chaste, and unpolluted during nine days; after which they came and offered sacrifices and prayers, wearing garlands of flowers called *ἱμερα*, and having under their feet *Διος κωδιον*, *Jupiter's skin*, which was the skin of a victim offered to that god. The person who assisted was called *ὑδρανος*, from *ὑδωρ*, *water*, which was used at the purification; and those purified were called *μυσται*, *the initiated.* A year after the initiation into the lesser mysteries they sacrificed a sow to Ceres, and were admitted into the greater, and the secrets of the festivals were solemnly revealed to them.

This festival was observed in the month Boedromion or September, and continued nine days, from the 15th till the 23d. During that time it was unlawful to arrest any man, or present any petition, on pain of forfeiting a thousand drachmas, or, according to others, on pain of death. It was also unlawful for those who were initiated to sit upon the cover of a well, and to eat beans, mullets, or weazels. If any woman rode to Eleusis in a chariot she was obliged by an edict of Lycurgus to pay six thousand drachmas. The design of this law was to destroy all distinction between the richer and poorer citizens. When the season approached, the mystæ, or persons who had been initiated only in the lesser mysteries, repaired to Eleusis to be instructed in the ceremonial. The service for the opening of the temple, with morning sacrifice, was performed, and the ritual was then produced from the sanctuary. It was enveloped in symbolical figures of animals, which suggested words compendiously, in letters with ligatures, the tops being huddled together, or disposed circularly like a wheel, and the whole utterly inexplicable to the profane. The case, which was called *petroma*, consisted of two stones exactly fitted; and the mysterious record, after being read, was closed up and replaced until a future festival. The principal rite was nocturnal, and confined to the temple and its environs. The mystæ waited without with impatience and apprehension. Lamentations and strange sounds were heard. Thunder pealed above these noises, and flashes of light and fire irradiated the gloom, rendering the darkness which followed more awful and sublime. The candidates for initiation were beaten by some invisible hand, whilst frightful apparitions, and monsters of a canine form, were presented to them, which filled them with apprehension and terror, and paralysed their energies. The scene then suddenly changed to one of a brilliant and agreeable character. The propylæa or vestibules of the temple were opened, the curtains withdrawn, and the hidden things displayed. They were introduced by the hierophant and daduchus, the former of whom revealed to them the mysteries. The splendour of illumination, the glory of the temple and of the images, and the singing and dancing which accompanied the exhibition, all contributed to soothe the mind after its recent agitation, and to render the wondering devotee tranquil and satisfied. After this inspection, or, as it was called, the *autopsia*, they retired, and others advanced. The succeeding days were employed in purification, in sacrifice, in pompous processions, and in spectacles, at which they assisted, wearing myrtle crowns. The second day was called *ἁλαδε μυσται*, *to the sea, ye initiated;* because they were commanded to purify themselves by ablution in the sea. On the third day sacrifices were offered, as also a mullet, and barley from a field of Eleusis. These oblations were called θυα, and were held so sacred that the priests themselves dared not, as in other sacrifices, partake of them. On the fourth day they made a solemn procession, in which the *καλαθιον*, or *holy basket of Ceres*, was paraded in a consecrated cart, while on every side the people shouted *χαιρε Δημητερ*, *Hail, Ceres.* After these followed women, called *κιστοφοροι*, who *carried baskets*, in which was sesamin, carded wool, grains of salt, a serpent, pomegranates, reeds, ivy boughs, and so on. The fifth was called *ἡ των λαμπαδων ἡμερα*, *the torch day*, because on the following night the people ran about with torches in their hands. It was usual to dedicate torches to Ceres, and contend who should offer the largest, in commemoration of the travels of the goddess, and of her lighting a torch in the flames of Mount Ætna. The sixth day was called Ιακχος, from Iacchus, the son of Jupiter and Ceres, who accompanied his mother in her search after Proserpine, with a torch in his hand. From this circumstance the hand of his statue was furnished with a torch, and carried in solemn procession from the Ceramicus to Eleusis. The statue, with those who accompanied it, called *Ιακχαγωγον*, was crowned with myrtle. In the way nothing was heard but singing and the noise of brazen kettles as the votaries danced along. The way through which they issued from the city was called *ἱερα οδος*, or *the sacred way*, the resting place *ἱερα συκη*, from a *fig-tree* which grew in the neighbourhood. They also stopped on a bridge over the Cephisus, where they derided those who passed by. After they had crossed this bridge, they entered Eleusis by a place called *μυστικη εισοδος*, or *the mystical entrance.* The seventh day was devoted to sports, in which the victors were rewarded with a measure of barley, that grain having been first sown in Eleusis. The eighth day was called Επιδαυριων *ἡμερα*, because Æsculapius on his return from Epidaurus to Athens was initiated by the repetition of the lesser mysteries. It became customary therefore to celebrate them a second time upon this occasion, in order that those who had not hitherto obtained the privilege might be lawfully initiated. The ninth and last day of the festival was called *πλημοχοαι*, or *earthen vessels*, because it was customary to fill two such vessels with wine, one placed towards the east, and the other towards the west; which, after the repetition of some mystical words, were both thrown down, and the wine spilt on the ground was offered as a libation.

The story of Ceres and Proserpine, the foundation of the Eleusinian mysteries, was both verbally narrated and represented in allegorical show. Proserpine was gathering flowers when she was stolen by Pluto; and hence the procession of the holy basket, which was placed on a car dragged along by oxen and followed by a train of females, some carrying the mystic chests, shouting *Hail, Ceres.* At night a procession was made with lighted torches, in order to commemorate the goddess searching for her daughter. A measure of barley, the grain which, it was believed, she had bestowed, was the reward of the victors in the gymnic exercises; and the proceedings at the temple had a reference to the legend. A knowledge of these things, from which the profane were excluded, formed the amount of what was communicated to the initiated; and the mode in which it was performed was skilfully adapted to the reigning superstitions. The operation was forcible, and the effect in proportion. The priesthood flourished as piety increased; and although the dispensation was corrupt, its tendency was not malignant. It produced sanctity of manners, an attention to the social duties, and a desire to be distinguished for what was then deemed virtue. (See *Divine Legation of Moses demonstrated;* Gibbon, in his *Miscellaneous Works*, on Virgil's account of Æneas's Descent into the Shades; and Heyne's *Excursus*, in reference to the same subject.)

ELEUSIS, a city of Attica, four leagues from Athens, and close to the shore opposite the island of Salamis. Like most of the other cities of Greece, its origin is ascribed to various fabulous characters, and, among these, to Ogyges; a circumstance which at least proves it to be of the highest antiquity. In the earlier period of its history it seems to have been an independent state, and was even so powerful as to contest with Athens itself the palm of superiority. A considerable portion of its small territory was occupied by the plains of Thria, remarkable for their fertility, though the hopes of the husbandmen were not unfrequently disappointed, from the blight of the south wind. To the west was the Campus Rharius, where Ceres is said to have sown the first seeds of corn; and on its confines was the field called Orgas, planted with trees consecrated to Ceres and Proserpine. The temple of Eleusis, sacred to Ceres and her daughter, was considered as one of the most beautiful productions of the genius of Greece; it is said to have been founded by Pandion II., and Clemens Alexandrinus places it even 120 years earlier, in the reign of Lynceus. Its position and riches naturally exposed it to the attacks of the enemies of Attica, and though defended by a strong fortress, it was seldom able to make any lengthened resistance. Cleomenes, king of Sparta, dared to violate its sacred precincts; but if we may believe the statements of the Athenians, he was soon overtaken by the just vengeance of the gods, and seized with a sudden fit of madness. The Persians burnt it to the ground after the battle of Platæa; but scarcely had they evacuated the confines of Greece, when the Athenians determined to rebuild it with even more than its original magnificence. Ictinus, the architect of the Parthenon, was ordered to draw up the plan of the new edifice. He adopted the Doric order of architecture, without the erection of pillars in front of the building. We know not whether he lived long enough to carry his plan into execution; but it was during the splendid administration of Pericles, and under the cultivated taste of Phidias, that the temple of Eleusis was completed in all its magnificence. The mystic cell was begun by Corœbus, but he lived only to finish the lower row of columns, with their architraves. Metagenes, of the district of Xypete, added the rest of the entablature and the upper row of columns. Xenocles of Cholargus built the dome on the top. A portico was long afterwards added by Demetrius Phalereus, who employed for that purpose the architect Philo. This magnificent structure continued to exist for many centuries, till the destructive hordes of Alaric completed its overthrow in the year 396. The city immediately disappeared on the destruction of the temple, which had been its ornament and principal support; and upon the site nothing is now found but a miserable village called *Lessina*, amidst the ruins of the sacred edifice. But the coins of Eleusis are still common, and represent Ceres drawn by dragons or serpents. The inscription is ΕΛΕΥΣΙ, or ΕΛΕΥ, within a wreath of ears of corn.

ELEUTHERIA, a festival celebrated at Platæa, in honour of Jupiter *Eleutherius*, or "the assertor of liberty," by delegates from almost all the cities of Greece. Its institution originated thus: After the victory which the Grecians under Pausanias obtained over Mardonius the Persian general, in the country of Platæa, an altar and statue were erected to Jupiter Eleutherius, who had freed the Greeks from the tyranny of the barbarians. It was further agreed upon, in a general assembly, by the advice of Aristides the Athenian, that deputies should be sent every fifth year from the different cities of Greece, to celebrate Eleutheria, or festivals of liberty. The Platæans celebrated also an annual festival in memory of those who had lost their lives in that famous battle. It was celebrated thus: At break of day a procession moved forward, headed by a trumpeter, who sounded a signal for battle; and after him followed chariots loaded with myrrh, garlands, a black bull, and certain free young men, no signs of servility being permitted to appear during the solemnity, because they in whose honour the festival was instituted had died in the defence of their country. They carried libations of wine and milk in large-eared vessels, with jars of oil and precious ointments; and the rear was brought up by the chief magistrate, who, although not permitted at other times to touch iron, or wear garments of any colour but white, yet on this occasion appeared clad in purple, and taking a water-pot out of the city chamber, proceeded through the middle of the town towards the sepulchres, with a sword in his hand. There he drew water from a neighbouring spring, and washed and anointed the monuments; after which he sacrificed a bull upon a pile of wood, invoking Jupiter and Mercury, and inviting to the entertainment the souls of those happy heroes who had perished on the plains of Platæa. After this he filled a bowl with wine, saying, I drink to those who lost their lives in the defence of the liberties of Greece. There was also a festival of the same name observed by the Samians in honour of the god of love. Slaves, also, when they obtained their liberty, kept a holiday, which they called *Eleutheria*.

ELEUTHEROLACONES, or INDEPENDENT LACONIANS, a name given to the twenty-four confederate towns of Laconia, the independence of which was confirmed by a decree of Augustus. At a much earlier date, when the power of Sparta had been broken and her freedom annihilated by the tyrant Nabis, Titus Quintius had detached the hamlets from all connection with Sparta, and placed them under the protection of the Achæan league. Augustus allowed these towns to be governed by their own laws, and to form a small distinct confederation. Of these twenty-four towns only eighteen are mentioned by Pausanias (iii. p. 21), probably because the others had gradually become depopulated.

ELEVATION, the same with altitude or height.

ELEVATION *of the Host*, in the church of Rome, that part of the mass where the priest raises the host above his head for the people to worship it.

ELEVATOR, in *Anatomy*, the name of several muscles, so called from their serving to raise the parts of the body to which they belong.

ELEVATORY, in *Surgery*, an instrument for raising depressed or fractured parts of the skull, to be applied after the integuments and periosteum have been removed.

ELEVE, a term purely French, though used also in our language. It signifies literally a disciple or scholar bred up under any master, being formed from an Italian word signifying an apprentice or novice. It was first used by the French writers in speaking of painters; such a painter was said to be an élève of Da Vinci, of Raffaelle, and so on. From painting it came to be applied to such as studied or learned any other art under a master. In the Royal Academy of Sciences there were twenty élèves; and in that of Inscriptions, ten élèves.

ELF, a term now almost obsolete, formerly used to denote a fairy or hobgoblin; an imaginary being, the creature of ignorance and superstition.

Elf-Arrows, in *Natural History*, a name given to the flints anciently fashioned into arrow-heads, and still found in Scotland, America, and several other parts of the world. It was believed by the vulgar that they were shot by fairies, and that cattle were sometimes killed by them.

ELFSBORG, a province in the southern part of Sweden. It is bounded on the north by Carlstadt, on the north-east by Wenar, on the east by Skaraborg, on the south-east by Jonkoping, on the south-west by Helmstadt, and on the west by Gotteborg. It extends over 3106 square miles, is divided into six bailiwicks, comprehends five cities, one market-town, and 4266 rural establishments, and contains 156,271 inhabitants. The land is generally mountainous and stony, or marshy and sandy, and yet produces corn nearly sufficient for the demand; but that demand is considerably lessened by the supply of potatoes, ruta baga, and other vegetables. It also produces some hemp and flax. The woods are the chief sources of the means of subsistence, by the employment they give to the labourers in cutting down, sawing, and conveying timber to the sea. The chief place is Wernersburg.

ELGANDEL, a town of Hindustan, in the Nizam's dominions, in the province of Hyderabad, ninety-five miles north-east from Hyderabad. Long. 79. 20. E. Lat. 18. 29. N.

ELGIN is the capital of Moray or Elginshire. It is a royal burgh, and returns a member to parliament along with Banff, Cullen, Peterhead, Inverury, and Kintore, Elgin being the returning burgh. It is a very thriving and improving town, containing about 5600 inhabitants. In approaching from Fochabers on the east, the traveller, viewing it from the bridge of Llanbryde, is struck with its beautiful appearance and fine situation. The town lies at the foot of the Lady Hill, and is overlooked by an elegant modern building, Gray's Hospital, with the Quarrywood Hill beyond, clothed with wood to the summit, the lower parts being covered with fine copses. The town chiefly consists of one principal street, named the High Street, with a few smaller ones intersecting it at various distances. The High Street is upwards of a mile in length from the New Institution to Gray's Hospital, which form beautiful terminations to it on the east and west. It is handsome and well paved, possessing many good houses and some rather elegant shops. Its width in the middle is so considerable, that a fine new church, lately built, stands in the middle of it, on the site of the old church of St Giles, and close to the Jail and Court-House, which are now about to be removed. Besides the new church, Elgin possesses various handsome public buildings, namely, the Academy, Gray's Hospital, Anderson's Institution, Trinity Lodge Rooms, Gas Works, &c. The Academy stands on the south side of the town, in a well-aired and central situation, and has become justly celebrated as one of the best in the north of Scotland. This academy is in a highly flourishing state in every respect, and is attended by nearly three hundred scholars of both sexes. A rector presides over the classical department; another master over that of mathematics and arithmetic, geography, &c.; and the third teaches English and elocution; whilst Mr Forbes, the Roman Catholic clergyman, unconnected with the Academy, gives private lessons in French and Italian. Gray's Hospital is a spacious and handsome edifice, surmounted with a dome, which, however, appears rather heavy and cumbersome. It stands on a gentle eminence at the west end of the High Street; it was built in 1816, and cost upwards of L.6000; and it contains from ten to thirty patients. Adjoining to this hospital a small Lunatic Asylum is now constructing, at the expense of the county; it is to be supported by annual contributions and voluntary donations, and attended by the hospital physicians. Anderson's Institution, for the education of youth and the support of old age, stands at the east end of the town. Its founder, the late General Anderson of the East India Company's service, was a native of Elgin, and at his death, a few years ago, bequeathed the bulk of his fortune, L.70,000, for the erection and support of this magnificent and truly benevolent institution, which was opened in 1833. This is a chaste and elegant pile of building, having a very handsome front, with pillars, and being surmounted by a dome, with an entablature, and piece of sculpture representing the benevolent founder in an attitude corresponding to his character. It contains ample accommodation for all connected with the establishment, and is capable of receiving many more, both old and young, than it now contains, when its revenue shall admit of an increase of numbers. In the construction of this building, as well as the new church, the beautiful free-stone of which they are built, and for which Morayshire is so famed, is shown to the greatest advantage. An infant school has also been lately opened, and is well attended. Trinity Lodge Rooms is a very handsome building in the North Street, and affords excellent accommodation for public meetings. The old Jail and Court-House, standing in the middle of the High Street, only deserves notice as being perhaps one of the worst in the kingdom; but there is at length a prospect of its being speedily removed, and better and more suitable accommodation provided both for the prisoners and courts of justice; notice having been already given that the town and county mean to apply for leave to obtain an act of parliament for the erection of a new one, in a better situation than the present.

The ruins of the cathedral, which was founded in 1224, once the most magnificent, and still one of the finest in the kingdom, is situated at the eastern extremity of the town. This noble cathedral was first destroyed by the Earl of Buchan. It was again rebuilt by the bishops of Moray; but in 1568 it was unroofed by order of the Regent Morton, for the sake of the lead. The ruins of this beautiful edifice have been lately put into excellent keeping, by order of the barons of exchequer. Around the cathedral stands the bishop's town house, now the property of the Duke of Gordon, whose family burial-place is in the cathedral; and also those of the dean and canons. The ruins of the Grey-Friars are on the south side of the town, and adjoining to the field where those of the old *Maison Dieu* were to be seen until very lately. At the west end of the town, the pretty green mount called Lady Hill affords an extensive and delightful view over the town and country, almost to Fochabers and the Spey. This hill bears distinct traces of having been an ancient fortification. It is said to have been used as a hunting seat by one of the Malcolms. The ruins show that it was built of stone and run lime, as used in early ages, and that the walls must have been of considerable thickness.

The trade of this town is at present not very considerable. A flourishing woollen manufactory has been carried on for many years, and employs fifty hands, chiefly in making blankets, plaiding, shawls, and drugget. There are likewise tan-works; and the glovers and sutors of Elgin were in former times famous for their extensive dealings at markets. Shoemakers are still a numerous body, and manufacture largely for the markets, which are held weekly on Fridays, and monthly on Tuesdays, the latter being for cattle and horses. The want of a good harbour at Lossiemouth, which is five miles distant, has long been a drawback to the increase of trade; but measures are now in progress to construct a new harbour, which, if successful, will give a great facility to the merchants in getting their goods directly from London, and to the farmers and corn-merchants in shipping grain, from twenty to thirty thousand bolls of which are exported from Morayshire annually. There is a literary association, combining the formation of a library with a public news-room, to which there are numerous subscribers; and a circulating library, established forty years ago by Mr Forsyth, and still successfully carried on by Forsyth and Young. There is also a mechanics' library, and one belonging to the academy, all highly useful establishments; and there is a weekly newspaper, the Elgin Courier, which has been published for five or six years.

Of benevolent institutions, several highly useful ones may be enumerated. A savings bank was instituted some years ago, and has been found to answer admirably. An excellent institution for female industry was lately formed, and has been found of great utility. Besides the Established Church, there is a Scotch Episcopal, an Antiburgher, and two Relief Chapels, with a few Roman Catholics. The improvements recently carried on in this town are numerous and considerable. A joint-stock company for lighting the streets and houses of the town with gas was formed about three years ago. Of late years several handsome new streets have been built, and on the south and west sides of the town many handsome villas and cottages have also been erected.

The town of Elgin is undoubtedly very ancient. By some historians its name is said to have been derived from Helgy, a Norwegian chief, who in the ninth century overran Morayshire. Other accounts derive it from the Saxon *Hely*, or Holy, and Dun, a hill. At the present time, perhaps, there are few towns in Scotland which possess equal attractions as a place of residence.

ELGINSHIRE, or MORAYSHIRE. See MORAYSHIRE.

ELGIN MARBLES is the name applied to that noble collection of sculptured figures which was acquired by the British Museum from Lord Elgin. They are mostly basso relievos and fragments of statuary which had adorned the Parthenon at Athens. The history of this collection may be thus shortly stated. It was in 1799 that the idea of such a collection first occurred to Lord Elgin, when he was appointed ambassador at Constantinople. Mr Harrison, an architect, suggested to him, in course of conversation, that though the public possessed every thing requisite to give them a general knowledge of the remains of Athens, yet to artists nothing but the actual representation by cast could be of essential service. Lord Elgin, struck with the truth of this observation, entered into communication with government on the subject; but the important transactions in which the nation was then engaged prevented ministers from undertaking an expense of so indefinite a nature. When Lord Elgin met Sir William Hamilton in Sicily, he entered with him into a more minute examination of the feasibility of the scheme, and they considered the best plan to be pursued in order to ensure success. It appeared to them most advisable that his lordship should be accompanied by artists from Italy. He accordingly obtained permission from the king of the Two Sicilies to take with him Signor Lusieri, a painter of great reputation, who was then in the service of that monarch; whilst he dispatched Mr Hamilton to Rome, in order to engage two architects, two modellers, and a figure painter. In the summer of 1800 these persons reached Athens in safety. At this period the French were in possession of Egypt, and the Turks felt little inclined to afford any facilities towards furthering the object which Lord Elgin had in view. They in fact did every thing to thwart him, and his artists could only obtain admission to the Acropolis, for the purpose of taking drawings, on the payment of a large daily fee. No sooner, however, did our arms prove victorious in Egypt, than a sudden and favourable change took place. The Sublime Porte showed an inclination to grant whatever our nation might think proper to ask; and Lord Elgin, availing himself of this opportunity, obtained, in the summer of 1801, firmans or warrants to the chief authorities of Athens, in which it was stated "that he might view, draw, and model the ancient temples of the idols, and the sculptures upon them, and make excavations, and *take away any stones* that might appear interesting to him." There was little difficulty after this permission had been granted; and as the Turks showed a perfect apathy in respect to the preservation of these remains, and indeed often wantonly destroyed them, Lord Elgin determined to remove as many as his means and the opportunity would allow. In this way did these noble remains of antiquity come into the possession of a British subject.

In 1811 an offer was made by Mr Percival to purchase the whole collection for the public, and the sum of L.30,000 was named as the price which the government was willing to give; but Lord Elgin thought this an inadequate compensation for the outlay occasioned in procuring the collection, and refused to listen to the proposal. In 1812 eighty more cases of architecture and sculpture were added, and also a collection of medals.

In 1815, however, Lord Elgin presented a petition to the House of Commons, in which he offered to make over the collection to the nation, on such conditions as it might seem just and reasonable to that assembly to recommend. Accordingly a select committee was appointed to examine into the affair, and after due consideration, and the examination of many witnesses, the committee came to the resolution of recommending the house to offer L.35,000 as a reasonable and sufficient price for this collection.

There can be no doubt that the House of Commons acted wisely in acceding to this proposition, and securing for the nation these noblest models which the genius of man has ever produced, knowing, as we do, how highly the cultivation of the fine arts has contributed to the reputation, character, and dignity of every government by which they have been encouraged, and how intimately they are connected with the advancement of every thing valuable in science, literature, and philosophy. No country is certainly better adapted than our own to afford an honourable asylum to these monuments of the school of Phidias, and of the wise administration of Pericles.

For further information, consult the *Report from the Select Committee on Lord Elgin's Collection of Sculptured Marble, &c.*; also the *Memorandum of the Earl of Elgin's Pursuits in Greece*, 4to, 1810. For an account of these marbles, see PARTHENON.

ELI, a high priest of the Israelites, and judge over them for forty years, was descended from Ithamar, a junior branch of the house of Aaron, and seems to have blended the priestly with the judicial character. He flourished in the year 1156 before the commencement of the Christian era. It appears that the Jews were in a state of subjection or vassalage to the Philistines during the greater part of Eli's administration, and, what may at first appear singular, he contributed to the degeneracy of his countrymen, although his own piety and goodness were unimpeachable. He did not exert his magisterial authority in the exemplary punishment of vice, and even permitted his own sons to perpetrate with impunity the most atrocious acts of impiety and debauchery.

The deity was so justly offended with this deportment of Eli, that a sacred seer was commissioned to upbraid him for his ingratitude and want of resolution. The young Samuel was likewise favoured with a vision of the approaching ruin of Eli's family, which he related to the venerable high priest, on being solemnly adjured not to conceal a single circumstance. When Eli heard the declaration of the young prophet, being fully convinced that his conduct had been highly reprehensible, he exclaimed, "It is the Lord; let him do what seemeth him good." Soon after this the Israelites sustained a considerable loss in attempting to procure their emancipation, carrying the ark of God into their camp in order to animate the people and intimidate their enemies; but the ark was captured by the Philistines, and Hophni and Phineas were slain. When intelligence was brought to Eli that the ark of God was taken, he instantly fell backwards from his seat, broke his neck, and died, in the ninety-eighth year of his age.

ELIJAH, who is sometimes denominated Elias, was one of the most distinguished of the Jewish prophets, and surnamed the *Tishbite*, probably from the district in which he was born. He entered upon his prophetic office about 920 years before Christ, in the reign of wicked Ahab, by whom the Sidonian idolatry was introduced amongst the Israelites. The prophet was commissioned to appear before this impious prince, and to threaten the country with a long drought as a punishment for his crimes. The indignation of Ahab was so great against the prophet for this prediction, that he resolved to punish him in a signal manner; but Elijah eluded his vengeance by withdrawing at the divine command, to a secret place, where he was supplied with provisions by a raven commissioned by heaven. He was afterwards ordered to go to Sarepta, in the territory of Sidon, where, in the house of an indigent widow, whose son he restored to life, the prophet was again supported in a miraculous manner.

When the three years of famine, occasioned by the continued drought, had expired, Elijah was commanded to appear before the king, and exhort him to that genuine repentance which an interposition of the deity so very remarkable unquestionably called for. He had an interview with Obadiah, the governor of the king's house, who was a religious man, and had frequently, at the hazard of his own life, screened many from the vengeance of Jezebel the queen. Inspired with dauntless fortitude, the prophet said to Obadiah, "Go, tell thy lord, behold Elijah is here." The good man's regard for the prophet was so great that he was afraid to deliver this message, alleging that Ahab had used every effort to discover the prophet's retreat. The king was however informed of his coming; and the first interview was distinguished by invectives on the part of the intrepid prophet and the proud sovereign, the former giving a promise of rain on the following terms: The priests of the Sidonian gods, and an assembly of the people of Israel, were to meet on Mount Carmel, where the prophet Elijah intended to give an incontestible proof of the almighty power of the God of Israel, and the total insignificance of the Sidonian divinities. For a detailed account of this memorable experiment, we must refer our readers to the book of Kings, as an abridgment of such a beautiful narration would do it manifest injury. It produced the fullest conviction in the minds of the Israelites that Jehovah alone was entitled to adoration; and the priests of Baal were instantaneously put to death, as the most abominable perverters of the divine law.

This was followed by abundance of rain, in answer to the devout prayers of the prophet; but his glorious triumph over idolatry so exasperated Jezebel, that she resolved to murder the prophet, who, in order to avoid her rage, fled into the wilderness, till the deity again employed him in the honourable but often hazardous duties of a prophet. He afterwards foretold that Hazael should be king of Syria, and Jehu king over Israel; and he appointed Elisha the son of Shaphat to be his own successor. He denounced dreadful judgments against Ahab and his wicked queen Jezebel; but those which respected the king were not executed during his life, on account of the genuine repentance which he discovered. The successor of Ahab having been confined to bed in consequence of an accident, the god of Ekron was consulted relative to his recovery, a circumstance which induced the prophet to declare that he should assuredly die. The king being informed that it was Elijah who dared to send such a message, dispatched a captain and fifty men to bring him by force into the royal presence; but they were destroyed by fire from heaven, and a second company shared the same fate. A third company confessed the visible interference of heaven in the prophet's behalf, the captain throwing himself on the mercy of Elijah, who went with him to the king. In the royal presence he undauntedly repeated the same denunciation against the idolatrous monarch, which was very soon accomplished; and not long after this the holy prophet, having, by the divine command, divided asunder the waves of Jordan, dropped his prophetic mantle to the astonished Elisha, took the flaming chariot commissioned for his reception, and ascended in majesty to heaven.

ELIS, or ELEA, a province in the north-west of the Peloponnesus, which was comprehended in its greatest extent between the promontory Araxus, where it touched on Achaia, and the river Neda, which separated it from Messenia. In the interior it was separated from Arcadia by the ridges of Mount Pholoë, and farther south by a continuation of the mountains from Arcadia.

In earlier times this tract of country was divided into three distinct principalities independent of each other. The most northern was surrounded by the lofty mountain Pholoë, which, sending out two ridges towards the coast, the one towards the promontory Araxus, the other towards the promontory Chelnatas, inclosed a large extent of champaign country, called from this circumstance the Hollow Elis (ἡ κοιλη Ηλις). The second principality was named Pisatis, and through its territories flowed the river Alpheus; whilst the district to the south was called Triphylia.

Elis was by far the most fertile and populous district of the Peloponnesus, chiefly because its extensive plains enjoyed an almost uninterrupted state of peace. Towards the coast the soil becomes sandy; a broad belt of sand stretches along the sea nearly as far as the Triphylian Pylos, so often called by Homer "the sandy." This tract of country is but little raised above the level of the sea, and from that reason a number of small lakes or lagoons have been formed, which extend along the greater part of the coast. It was the only district in Greece which produced flax; but this, though equal in fineness, was far inferior in colour, to that of Palestine. Another extraordinary circumstance was, that no mules could be here engendered, though they abounded in the adjacent district.

At a very early period we find it under the government of Endymion, and called the kingdom of the Epei. Homer was acquainted with the divine Elis, where the Epei ruled. His son Ætolus having accidentally committed a murder, was obliged to fly, and proceeded to found a kingdom on the opposite coast, called from him Ætolia. He was succeeded by Eleus, the grandson of Endymion, who gave name to the country, and after him came Augeas, who was put to death by Hercules because he refused him the reward he had promised for clearing out his stables. We now lose sight of Elis till the irruption of the Heraclidæ into Greece, eighty years after the destruction of Troy, when Oxylus, a descendant of Ætolus, offered to become their guide, on condition of receiving the province of Elis, which he considered as the inheritance of his family. A numerous body of Ætolians attended him, and uniting cordially with the native inhabitants of Elis, they conquered a great part of Pisatis, and took possession of Olympia about 1190 before Christ. Then it was that the Olympic games were first established on the banks of the river Alpheus, though they were not regularly celebrated till the year 776 before Christ, when Corœbus obtained the prize of victory. In the wars between Messenia and Sparta, they were faithful allies of the latter; and with their assistance they took possession of the whole country belonging to the Caucones and Minyæ, to which the name of Triphylia was then given. During the Peloponnesian war, we still find them staunch supporters of Spartan politics; and they continued so till the conclusion of the treaty after the battle of Amphipolis, when the countenance afforded by the Spartans to the independent movements of the people of Lepreum produced a rupture between the two nations. Elis endeavoured to take vengeance on the Spartans, by excluding them from all participation in the Olympic games; but the marauding invasions of the Spartans were soon so severely felt, that the inhabitants of Elis were glad to sue for peace, and to renew their ancient alliance with Sparta. In the year 365 before Christ, a few years after the battle of Leuctra, they were engaged in war with the Arcadians, and were so unsuccessful that they were compelled to cede the greater portion of their southern possessions. During the Social War, the Eleans were staunch allies of the Ætolians, and no reverses could detach them from the cause which they had joined, or induce them to unite with the Achæan League. These seem to have been the last events in which the Eleans took part as an independent people; and we find them finally included in the general decree which annexed the whole of Greece to the Roman empire.

Elis, the chief city of the district of Elis, in the Peloponnesus, situated on the banks of the river Peneus, 120 stadia from the sea, and first formed into a district corporation by the union of several detached villages after the Persian war, about 490 years before Christ. The people of this portion of Greece had for ages been devoted to the pleasures of a country life, and they had been able to indulge this natural desire by the sacred character which had been long attached to their territory. At the time when Oxylus got possession of this fertile province, and became master of the temple of Olympia, he had such influence with the Heraclidæ as to obtain from them the sanction of an oath that this district should be considered as under the immediate protection of the god whose festival was there solemnized. This seems to have been so strictly attended to that those who founded the city did not think it necessary to surround it with walls, or to take any steps to ward off the attack of an enemy. In the unsettled times which followed the death of Alexander, Elis was occupied, and probably fortified, by Telesphorus, who commanded the fleet of Antigonus. (Diodor. xix. 87; Strab. viii. 357; Xen. Hall. iii. 2, 20.) It appears, in the time of Pausanias, to have still retained much of its former beauty and magnificence, if we may be allowed to judge from the account he has left us of the public buildings. "Its ruins," says he, "are found now at a spot called *Paleopoli*, consisting of several masses of Roman tile and mortar, with many wrought blocks of stone and fragments of sculpture scattered over a space of two or three miles in circumference. The most remarkable of the ruins is that of a square building of about twenty feet on the outside, which is in the form of an octagon with niches. Like most of the other remains, it is built of alternate strata of Roman tile and stone rubble." (Leake's *Morea*, vol. i. p. 6.)

ELISHA the prophet, famous for the miracles which he performed, died about 830 years before Christ.

ELISION, in *Grammar*, the cutting off or suppressing a vowel at the end of a word, for the sake of sound or measure, the next word beginning with a vowel. Elisions are pretty frequently met with in English poetry, but oftener in the Latin, French, Italian, and other languages. They consist chiefly in the suppression of the *a*, *e*, and *i*, though an elision suppresses any of the other vowels.

ELIXATION, in *Pharmacy*, the extracting of the virtues of ingredients by boiling or stewing.

ELIXIR, in *Medicine*, a compound tincture extracted from many efficacious ingredients. Hence the difference between a tincture and an elixir seems to be this, that a tincture is drawn from one ingredient, sometimes with an addition of another to open it and to dispose it to yield to the menstruum; whereas an elixir is a tincture extracted from several ingredients at the same time.

ELIZABETH, queen of England, daughter of Henry VIII. and Anne Boleyn, was born at Greenwich, on the 7th of September 1533. According to the custom of the times, she was early instructed in the learned languages, first by Grindal, who died when she was about seventeen, and afterwards by the celebrated Roger Ascham. She likewise acquired considerable knowledge of the Italian, Spanish, and French languages. Dr Grindal was also her preceptor in divinity, which she is said to have studied with uncommon application and industry. That Elizabeth became a Protestant and her sister Mary a Catholic, was the effect of that cause which determines the religion of the greater part of mankind, namely, the opinion of those by whom they were educated; and this difference of opinion in their tutors is not at all surprising, when we recollect that their father Harry was of both religions, or of neither.

But the studies of Elizabeth were not confined merely to languages and theology; she was also instructed in the political history of the ancients; and was so well skilled in music as to sing and play "artfully and sweetly."

After the short reign of her brother Edward, her sister Mary succeeding to the crown, Elizabeth experienced a considerable degree of persecution, so as to be not a little apprehensive of a violent death. She was accused, imprisoned, and, we are told, inhumanly treated. At last, by the intercession of King Philip of Spain, she was set at liberty; which she continued to enjoy, till, on the death of her sister, she, on the 17th of November 1558, ascended the throne of England. Her history as a queen is detailed in the article England. The cares of government did not wholly suspend her pursuit of learning. Ascham, in his *Schoolmaster*, tell us that about the year 1563, five years after her accession, she read more Greek in one day than some prebendaries of that church did read Latin in a whole week. That the Latin language was familiar to her, is evident from her speech to the university of Oxford, when she was nearly sixty, and also from her spirited answer to the Popish ambassador in the year 1598. And that she was also skilled in the art of poetry, appears not only from the several scraps which have been preserved, but likewise from the testimony of a contemporary writer, Puttenham, in his *Art of English Poetry.* These are his words: "But last in recital and first in degree is the queen, whose learned, delicate, noble muse, easily surmounteth all the rest, for sense, sweetness, or subtility, be it in ode, elegy, epigram, or any other kind of poem." In this author are to be found only a specimen of sixteen verses of her English poetry. "But," says Mr Walpole, "a greater instance of her genius, and that too in Latin, was her extempore reply to an insolent prohibition delivered to her from Philip II. by his ambassador, in this tetrastic.

> Te veto ne pergas bello defendere Belgas:
> Quæ Dracus eripuit, nunc restituantur oportet:
> Quas pater evertit, jubeo te condere cellas:
> Religio papæ fac restituatur ad unguem.

She instantly answered him, with as much spirit as she used to return his invasions,

> Ad Græcas, bone rex, fient mandata kalendas."

She died in her palace at Richmond, the 24th of March 1603, aged seventy, having reigned forty-four years; and was interred in the chapel of Henry VII. in Westminster Abbey. She was the author of the following works: 1. The Mirror, or Glass of the Sinful Soul, which she translated from French verse into English prose when she was eleven years old. The translation was dedicated to Queen Catharine Parr. Probably it was never printed; but the dedication and preface are preserved in the *Sylloge Epistolarum*, in Hearne's edition of *Livii Foro-Juliensis*, p. 161. 2. Prayers and Meditations, dedicated to her father, and dated at Hatfield, 1545. Manuscript in the Royal Library. 3. A Dialogue from Xenophon, between Hiero a king yet some time a private person, and Simonides a poet, touching the life of the prince and the private man. This was first printed from a manuscript in her majesty's own handwriting, in the Gentleman's Magazine for 1743. 4. Two Orations of Isocrates, translated into Latin. 5. Latin Oration at Cambridge, preserved in the king's library; also in Hollinshed's Chronicle, and in Fuller's History of Cambridge. 6. Latin Oration at Oxford. 7. Comment on Plato. 8. Boethius *De Consolatione Philosophiæ*, translated into English anno 1593. 9. Sallust *De Bello Jugurthino*, translated into English anno 1590. 10. A Play of Euripides, translated into Latin. 11. A Prayer for the use of her fleet in the great expedition in 1596. 12. Part of Horace's Art of Poetry, translated into English anno 1598. 13. Plutarch *De Curiositate*, translated into English. 14. Letters on various occasions to different persons. 15. Several Speeches to her Parliament; and a number of other pieces. (See Wood's *History and Antiquities of Oxford;* and Walpole's *Catalogue of Royal and Noble Authors.*)

ELIZONDO, a town of Spain, in the province of Navarre. It is the capital of the district of the Valley of Bastan, near Roncesvalles, which enjoys some peculiar privileges; and is situated in a cold country, near the Pyrenees, which produces wheat, maize, hemp, and flax. Many turnips are grown in this district; and it has excellent cider, but no wine. Lat. 43. 9. 43. N.

ELK, in *Zoology*. See MAMMALIA.

ELL (*ulna*), a measure which obtains, under different denominations, in most countries, and by which cloths, stuffs, linens, silks, and the like, are usually measured, answering nearly to the yard of England, the canna of Italy, the vara of Spain, and the palm of Sicily. See WEIGHTS AND MEASURES.

ELLBOGEN, a circle in the Austrian kingdom of Bohemia, extending over 1343 square miles, and comprehending forty-three cities and towns and 609 villages, with 32,829 houses and 193,537 inhabitants. The chief town, of the same name, stands on a steep rock, at the foot of which runs the river Eger, which makes a bend that nearly surrounds it. It contains 457 houses, with 1508 inhabitants, who subsist by handicraft employments, and by the preparation of alum and of sulphur.

ELLESMERE, a market-town of Shropshire, in the hundred of Pimhill, 242 miles from London. The name is derived from a beautiful lake or meer, near to which it is situated. From Ellesmere castle there is a fine prospect extending over the surrounding counties, none of which, it is said, can be seen from it. A navigable canal connects the town with the Mersey. The market is held on Tuesday. The population amounted in 1801 to 5553, in 1811 to 5639, in 1821 to 6056, and in 1831 to 6540.

ELLICHPOOR, a town of Hindustan, in the province of Berar. It was first acquired by the Mahommedans in 1294, and is the proper capital of Berar, Nagpoor being of recent date. The travelling distance from Nagpoor is 122 miles, from Delhi 604, from Madras 671, and from Calcutta 844 miles.

ELLIOT, THE RIGHT HONOURABLE GEORGE AUGUSTUS, Lord Heathfield, was the youngest son of Sir Gilbert Elliot, Baronet, of Stobbs, in Roxburghshire, and was born about the year 1718. He received the rudiments of his education under a private tutor, and at an early period of life was sent to the university of Leyden, where he made considerable progress in classical learning, and spoke with fluency and elegance the German and French languages. Being designed for a military life, he was sent from thence to the celebrated *Ecole Royale du Génie Militaire*, conducted by Vauban, at La Fère in Picardy, where he laid the foundation of that science which he so conspicuously exhibited at the defence of Gibraltar He completed his military course on the Continent by a tour, undertaken for the purpose of seeing in practice what he had studied in theory. Prussia was the model for discipline, and he continued some time as a volunteer in the service of that state.

Mr Elliot returned, in the seventeenth year of his age, to his native country, Scotland; and was the same year, 1735, introduced by his father Sir Gilbert, to Lieutenant-Colonel Peers of the twenty-third regiment of foot, then stationed at Edinburgh, as a youth anxious to bear arms for his king and country. He was accordingly entered as a volunteer in that regiment, where he continued for upwards of a year. From the twenty-third regiment he went into the engineer corps at Woolwich, and made great progress in study, until his uncle Colonel Elliot appointed him adjutant of the second troop of horse grenadiers. With these troops he went upon service to Germany, and was present with them in a variety of actions. At the battle of Dettingen he was wounded. In this regiment he obtained the rank of captain and major, and afterwards purchased the lieutenant-colonelcy. On arriving at this grade he resigned his commission as engineer, which he had enjoyed along with his regimental rank, and quitted a branch of the service in which he had been actively employed very much to the advantage of his country. He received the instructions of the famous engineer Bellidor, and made himself completely master of the science of gunnery; and had he not so disinterestedly resigned his rank in the engineer department, he would long before his death have, by regular progression, reached the head of that corps. Soon after this he was appointed aid-de-camp to George II. and was distinguished for his military skill and discipline. In the year 1759 he quitted the second troop of horse grenadier guards, being selected to raise, form, and discipline, the first regiment of light horse, which was called after him *Elliot's*. As soon as they were raised and formed he was appointed to the command of the cavalry in the expedition on the coasts of France, with the rank of brigadier-general. After this he passed into Germany, where he was employed on the staff, and greatly distinguished himself.

During the peace he was not idle. His great talents in the various branches of the military art procured him ample employment. In the year 1775 he was appointed to succeed General A'Court as commander-in-chief of the forces in Ireland; but he did not continue long on this station, not even long enough to unpack all his trunks; for finding that interferences were made by petty authority derogatory of his own, he resisted the practice with becoming spirit; and not choosing to disturb the government of the sister kingdom on a matter personal to himself, he solicited to be recalled. The government acceded to his request, and, in a fortunate hour for the safety of Gibraltar, he was appointed to the command of that important fortress. The system of his life, as well as his education, peculiarly qualified him for this trust. He was perhaps the most abstemious man of the age, indulging himself neither in animal food nor in wine. He never slept more than four hours at a time, so that he was up later and earlier than most other men. He so inured himself to habits of hardiness, that the things which prove difficult and painful to other men were to him his daily practice, and rendered pleasant by use. It could not be easy to starve such a man into a surrender, nor possible to surprise him. The example of the commander-in-chief in a besieged garrison has the most persuasive efficacy in forming the manners of a soldiery. Like him, his brave followers came to regulate their lives by the most strict rules of discipline before there arose a necessity for so doing; and severe exercise, with short diet, became habitual to them from their own choice. The military system of discipline which he introduced, and the preparations which he made for his defence, were contrived with so much judgment, and executed with so much address, that he was able with a handful of men to preserve his post against an attack, the constancy of which, even apart from the vigour with which it was made, would have been sufficient to exhaust any common set of men. Collected within himself, he in no instance attempted by premature attacks to destroy the labours which it would cost the enemy time, patience, and expense to complete; he deliberately observed their approaches, and, with the justest discernment, seized on the proper moment at which to make his attack with success. He never spent his ammunition in useless parade or in unimportant efforts. He never relaxed his discipline from the appearance of security, nor hazarded the lives of his garrison by wild experiments. By a cool and temperate demeanour, he maintained his station for three years of constant investment, in which the whole powers of Spain were employed against him. All the eyes of Europe were on this garrison; and his conduct has justly exalted him to the most elevated rank in the military annals of his time. On his return to England, the gratitude of the British senate was as forward as the public voice in awarding him that distinguished honour which his merit deserved. Both houses of parliament voted an unanimous address of thanks to the general; the king conferred on him the honour of knight of the bath, with a pension during his own and a second life of his own appointment; and on the 14th June 1787, his majesty advanced him to the peerage by the title of Lord Heathfield, Baron Gibraltar, permitting him to take, in addition to his family arms, the arms of the fortress which he had so bravely defended.

His lordship died on the 9th of July 1790 at Aix-la-Chapelle, of a second stroke of the palsy, after having for some weeks preceding enjoyed tolerable good health and an unusual flow of spirits. His death happened two days before he was to have set out for Leghorn on his way to Gibraltar, of which place he was once more appointed governor, in the view of an approaching war. He married Anne, daughter of Sir Francis Drake of Devonshire, and had by her Francis Augustus, by whom he was succeeded in his title.

ELLIPSIS, in *Grammar*, a figure of syntax, in which one or more words are not expressed; and from this deficiency it has got the name of *ellipsis*.

ELLIPTIC, or ELLIPTICAL, something belonging to an ellipsis.

ELLIPTIC TURNING. Wood and other substances are turned into an elliptic form by means of a chuck, which is applied on the common turning lathe. This chuck is on the principle of the trammel, Plate CCXVIII. fig. 1. The grooves in the chuck are much wider than in the trammel, and the points of the chuck that correspond to C, D of the trammel, fig. 1, remain fixed, and in one horizontal line; whereas in the trammel these are the points which are put in motion.

Illustration of the principle.

If two straight lines, crossing each other, be drawn on a piece of transparent paper or mica; if this transparent paper be laid upon a sheet of white paper, with two points marked on it; if the transparent paper be moved round, so that the cross lines shall travel over the two points, in like manner as the two points C, D in the trammel, fig. 1, travel over the cross grooves of the trammel; and if the point of a pencil be held fixed, and touching the transparent paper, so as to leave a trace on the transparent paper when the paper is moved; then after the transparent paper has made a revolution, the trace left on it by the point of the pencil will be an ellipse. This method of describing an ellipse represents the action which takes place in the chuck for turning ellipses; the point of the pencil which remains unmoved is in the same situation as the turner's gouge; the transparent paper which receives the trace of the ellipse from the fixed pencil is analogous to the wood, which is to be turned into the form of an ellipse by the fixed cutting gouge.

Description of the chuck.

In fig. 2, the chuck is represented as fitted on a common turning lathe, of which A is the pulley of the maundrel, B and C are the sides of the frame supporting the pulley, P the rest, D the frame in which the rest slides, E, F the feet of that frame, I the nut and screw which serve to fix the rest, G, H are the continuation of the sides B, C. K is the elliptic chuck, with two grooves, through which the knobs of the slider pass. These knobs are connected by a strong bar of iron screwed into their ends; and on this bar of iron is seen the screw for fastening the board, to which is fixed the wood or other substance which is to be turned elliptically.

Fig. 3 shows the other side of the chuck, which in fig. 2 is turned towards the side of the frame C. N, in fig. 3, is the board with the grooves which contain the slider O. In the middle of N is seen the end of the screw, which is fixed to the maundrel. The board N has a circular motion, being fixed on the axis of the maundrel, whilst the slider O, at the same time that it is carried round by the circular motion of N, is constrained to perform other motions by the grooves in N and by the groove in O, fig. 3, which slides on the ring M, fig. 4.

In fig. 4, L is a part of the side C of the maundrel frame, with the ring M fastened to it. On this ring the broad groove in the slider O, fig. 3, moves when the lathe is set agoing; and this groove is at right angles to the grooves in N, fig. 3, in which the knobs of O move. In fig. 4 it is seen that the centre of the ring M may be made to coincide with the centre of the spindle of the maundrel, in which case a circle is described. If the ring is fixed, so that the centre of the ring does not coincide with the centre of the maundrel, an ellipse is described by the wood screwed upon the bar of O in fig. 2; and the most eccentric ellipse that the machine describes is obtained when the maundrel is at the circumference of the ring. The centre of the spindle of the maundrel, and the centre of the ring M, are always in one immoveable horizontal line, and are analogous to the points C, D of the trammel, fig. 1. In fig. 3 it is seen that the sides of the grooves may be brought nearer together by means of screws; so that the sliders and the cylindric ring may fit exactly to the grooves. The best elliptic chucks are made of brass. See *Mechanical Exercises*, by Peter Nicholson, London, 1812. (B. B.)

ELLIPTOGRAPH, an instrument for drawing ellipses. The trammel is an instrument which has long been known and used for describing ellipses. On the principle of the trammel Mr Farey constructed his elliptograph in a form much more commodious for drawing. Mr Farey's elliptograph is represented at Plate CCXVIII. fig. 5. The circle A slides between the two parallel rulers D, E. The circle B slides between two parallel rulers F, G, at right angles to the former. In this way, if a line joining the centres of the circles is made to revolve, M, the extremity of that line, will describe an ellipse in the same manner as the extremity E of the line CDE, fig. 1, does in the trammel. The elliptograph may be considered as a trammel, in which the pins C and D, fig. 1, are enlarged into the circles A and B, fig. 5. The pinion at K, fixed to one of the arms of the lower circle, acting on a rack screwed to the upper circle, serves to alter the distance of the centres of the circles A and B; and, by so doing, this pinion serves to vary the eccentricity of the ellipses which the instrument describes. When the centres of the circles A, B coincide, the describing pen M draws a circle. When the centres are removed from each other, and on the circles being turned round, an ellipse is described by the pen; and when the distance of the centres in increased, the eccentricity of the ellipse is increased. When the pen is at the centre it describes a straight line, continually moving to and fro on that line when the circles are turned round. The two circles are fixed together by screws, and can only be made to slide the upper circle over the lower by the action of the pinion K. The pinion at L moves a rack, by which the describing pen M, which draws the ellipse, is brought nearer to the centre for the purpose of drawing a small ellipse, and removed farther from the centre of the ellipse when a large one is to be drawn. The size of the ellipse may be increased as far as the size of the instrument will admit. The pair of rulers D, E are placed below the pair F, G, as is seen in fig. 6. The instrument, when used, is held upon the paper with the thumb and a finger of the left hand at the nuts N, O; and the circles are moved by applying the right hand to the pins *f*; the pen M, pressing by its weight on the paper, then describes the ellipse.

Fig. 7 shows H, the socket for the compasses, with the centre pin on which the socket moves; and the pinion L and rack *h*, for moving along the frame *g* between the bars; and the other pinion K, for separating the circles.

The ruler P has two points, to fix the instrument to the paper. The ruler is united to the frame by screws, which serve to adjust the position of the instrument after the ruler has been fixed to the paper.

Mode of using the instrument.

By means of the elliptograph any ellipse can be described, of which the long and short axes are given, provided it does not exceed the size of the instrument. When an ellipse is to be described, draw on the paper the longer and shorter axes, bisecting each other; place the instrument on the paper, so that the centre of the four rulers appears to coincide with the centre or the intersection of the two axes of the ellipse; and fix the instrument in this situation by the points that go into the paper. By the pinion L move the pen to one extremity of the short axis of the ellipse; turn the circles half round, to see if the pen comes to the other end of the short axis; if it does not, adjust the error one half, by moving the pen by the pinion L, the other half by moving the frame on the paper; continue this adjustment till the pen, setting out from the one end of the short axis, arrives in a half revolution at the other end. Next, by means of the pinion K, bring the pen to one end of the long axis of the ellipse; turn the circles half round, and if the pen reaches the other extremity of the long axis of the ellipse, the instrument is rectified; if not, one half of the error is to be corrected by moving the circles by means of the pinion K, and the other half by moving the instrument to a side on the paper, by means of the nuts N, O. The instrument is now adjusted, and the pen resting on the paper traces the ellipse required when the circles are turned round by the handles.

Elliptograph for engraving.

An instrument similar to the elliptograph has been employed for engraving ellipses on copper plates, and for dividing these ellipses accurately, so as to give the perspective representation of a circle divided into equal parts, both in the case where the distance of the eye is limited, and in the orthographic projection. The Society for Encouraging Arts rewarded Mr Farey with their gold medal for his invention, and a description of the elliptograph is contained in the thirty-first volume of the Transactions of that society. (B. B.)

ELLMORE, a town of Hindustan, in the northern circars, and district of Cicacole, twenty miles N.N.E. from the town of Cicacole. Long. 84. 10. E. Lat. 18. 24. N.

ELLORE, a town of Hindustan, capital of the northern circar of the same name. Long. 81. 10. E. Lat. 16. 45. N. The circar is situated principally between the sixteenth and seventeenth degrees of north latitude. The principal towns are Ellore, Colaircotta, and Gundgoli.

ELLRICH, a city of Prussia, in the government of Erfurt and circle of Hohenstein. It stands on the river Zorge, and contains 470 houses, with 2820 inhabitants, who find employment in woollen manufactories, tanneries, and paper and oil mills. About two miles from it is the celebrated cavern called Hartzhole. It is 290 feet long, 260 broad, and 156 high. The entrance to it is 150 feet high, and it is filled with water to the depth of 50 feet.

ELLWANGEN, a bailiwick of the circle of the Jaxt, in the kingdom of Wirtemberg, comprehending two cities, one town, and two hundred and thirty-four villages, with 25,337 inhabitants. It is better adapted for pasture than for corn. The capital is a city of the same name, situated on the Jaxt, in which is a gymnasium and high school. It contains eleven churches, 408 houses, and 2590 inhabitants. Long. 9. 57. E. Lat. 48. 58. N.

ELLYS, DR ANTHONY, who was born in 1693, and educated at Clarehall, Cambridge, after rising through many inferior degrees of dignity in the church of England, was in 1752 promoted to the see of St David's. He died at Gloucester in 1761, and is mentioned here only on account of his works, which are but little known. They are as follow: 1. A Plea for the Sacramental Test as a just security to the Church established, and very conducive to the welfare of the State; 2. Remarks on Hume's

Essay on Miracles; 3. Tracts on the Liberty spiritual and temporal of Protestants in England, addressed to J. N., Esq. at Aix-la-Chapelle, the first part of which was printed in 1763, and the second in 1765; besides occasional sermons. In these tracts, as the editors of them truly observe, he " discovers not only fine parts, extensive knowledge, and sound judgment, but a heart overflowing with benevolence and candour, and a most Christian temper; for he always thought a person, though on the right side of the question, with principles of persecution, to be a worse man than he that was on the wrong." This amiable and respectable writer afforded in his own conduct a proof that a man may be steadily attached to a party without wishing to encroach upon the rights of others.

ELMACINUS, Elmacin, or Elmakyn, George, author of a *History of the Saracens*, and known in the East by the name of Ibn-Amid, was a Christian of Egypt, where he was born in the year of the hegira 620, and of our era 1225. He occupied the place of ketib or secretary at the court of the sultans of Egypt; an office which was usually filled by Christians. His history comes down from the time of Mahommed till the year of the hegira 512, answering to the year of our Lord 1117; in which he sets down year by year, in a very concise manner, whatever regards the Saracen empire, intermixed with some passages relating to the eastern Christians. His abilities must have been considerable, since, as we have just seen, he held an office of trust near the persons of the Mahommedan princes. He was son to Yaser Al Amid, secretary to the council of war under the sultans of Egypt for forty-five years; and in 1238, when his father died, succeeded him in his place. He died at Damascus in the year of the hegira 675, and of our era 1273. His history of the Saracens was translated from Arabic into Latin by Erpinius, and printed in both languages at Leyden, 1625, in folio. Erpinius died before the publication was completed; but Golius superintended it, and added a preface. It was dedicated by Erpinius's widow to Dr Andrews, bishop of Winchester. The title of the work is, *Historia Saracenica, quâ res gestæ Muslimorum, inde a Muhammede primo imperii et religionis Muslimicæ auctore, usque ad initium imperii Atabecæi, per XLIX. imperatorum successionem fidelissime explicantur, insertis etiam passim Christianorum rebus in Orientis potissimum ecclesiis eodem tempore gestis.* Arabice olim exarata a G. Elmacino et Latine reddita. Leyden, 1625, 8vo. The Latin text was printed separately the same year, in quarto; and there also exists an edition which only contains the Arabic text, and appears to have been designed for the Christians of the Levant. The work has been translated in whole or in part into several modern languages.

ELOGY, a praise or panegyric bestowed on any person or thing, in consideration of its merit. The beauty of elogy consists in an expressive brevity. Eulogiums should not have so much as one epithet, properly so called, nor two words synonymous; they should strictly adhere to truth, as extravagant and improbable elogies rather tend to lessen than exalt the character of the person or thing they would extol.

ELOHI, Eloi, or Elohim, in Scripture, one of the names of God. But it is to be observed that angels, princes, great men, judges, and even false gods, are sometimes called by this name. The sequel of the discourse is what assists us in judging rightly concerning the true meaning of this word. It is the same as *Eloha*, only the one is the singular and the other the plural. Nevertheless *Elohim* is often construed in the singular number, particularly when the true God is spoken of; but when false gods are spoken of, it is construed rather in the plural.

ELOINED, in *Law*, signifies restrained or hindered from doing something. Thus it is said, that if those within age be eloined, so that they cannot sue personally, their next friend shall sue for them.

ELONGATION, in *Astronomy*, the digression or recess of a planet from the sun, with respect to an eye placed on our earth. The term is chiefly used in speaking of Venus or Mercury, the arch of a great circle intercepted between either of these planets and the sun being called the *elongation* of that planet from the sun.

ELORA, a town of Hindustan, in the province of Aurungabad, near the city of Dowletabad. In a mountain near this town there are some remarkable excavations, containing mythological symbols of the Hindu worship, and temples ornamented with representations and statues of many of the deities worshipped by the Hindus. The principal figures are those of Indra, the god of the firmament, and his consort Indranee. Besides these, there are some figures of the deities adored by the sectaries of Boodh and Parisinath; but all of them have been forsaken by the priests. The temples here are said to have been built by the rajah Edoo of Ellichpoor, who was cured of some cutaneous disorders by a spring near the place, and who in gratitude gave orders for the construction of the temple, which measures 138 feet in front, and in the interior extends 247 feet in length by 150 feet in breadth, and is in some places 100 feet high. The sixth volume of the *Asiatic Researches* contains a minute account of these curious antiquities. Long. 76. E. Lat. 19. 56. N.

ELPHINSTONE, William, a Scotish prelate and statesman of considerable eminence, was born at Glasgow in the year 1431. At the university of this city he received his education, and in the learning which distinguished the period he made extraordinary proficiency. He afterwards went to France, to make himself master of the civil and canon law in the university of Paris, where in due time he became a professor, and for the space of six years acquired reputation in the discharge of his duty. On his return to Scotland he entered into holy orders, was soon appointed official of Glasgow, and afterwards of St Andrews. He was admitted a member of the king's council; and on a misunderstanding taking place between James III. of Scotland and Louis XI. of France, his powerful mediation at the latter court, in conjunction with the Bishop of Dunkeld and the Earl of Buchan, effected an amicable reconciliation. As Elphinstone on this occasion displayed much prudence and eloquence, the king was so grateful for his meritorious services that he rewarded him with the see of Ross, from which he was translated to that of Aberdeen about the year 1484. He was also appointed to the high office of chancellor of the kingdom, which he managed with so much moderation and equity that all parties esteemed and admired him. When the civil wars broke out between James and the discontented nobility, Bishop Elphinstone appears to have declined all interference with public affairs of a political nature, and to have confined himself to the discharge of his episcopal duties. But when James IV. ascended the throne, his abilities as a statesman were again called forth, and he was chosen ambassador to the Emperor Maximilian, in order to negociate a marriage between his royal master and the emperor's daughter; but she had been previously promised to another. Yet the bishop's mission was not without its salutary effects, as he was the mean of terminating an enmity which had long existed between the Dutch and Scots. This he conducted in such a masterly manner, that James never undertook any thing of importance without first procuring the sanction of his approbation. He was equally the zealous patron of learning; and it is generally believed that the establishment of a university at Aberdeen was entirely owing to his influence with the pope, from whom he obtained a bull for that purpose; and by his exertions was King's College undertaken and completed. Having bequeathed a large sum of money for its support, he terminated his mortal career in 1514. Although he had attained the age of about eighty-three, his constitutional vigour was very little impaired, and all the faculties of his mind were in full force; but the calamity which the nation sustained at Floddon-field had broken his heart. He wrote a history of his native country, which is among the manuscripts of Sir Thomas Fairfax, in the Bodleian Library at Oxford.

ELPISAN, a town of Asiatic Turkey, in the province of Diarbekir, situated on the river Euphrates, two miles north-west of Kerkisieh.

ELSFLETH, a town in the duchy of Oldenburg, in Germany, at the conflux of the Hunte and the Weser. It contains 192 houses, and 1562 inhabitants. The vessels which frequent this port anchor lower in the river, near Brake. Long. 8. 21. 5. E. Lat. 53. 14. 50. N. It is the capital of a bailiwick, with six parishes, 1135 houses, and 7510 inhabitants.

ELSINEUR, a city of Denmark, in the island Zealand. It was formerly a Hanse town, and is now the second city in Denmark proper. It is strongly fortified, and has a castle, Cronburg, designed to command the entrance of the Baltic Sea by the Sound; but in the English attacks on Copenhagen it was found of no avail. The passage of ships, who pay a toll, makes the town active and prosperous. It contains 552 houses and 5000 inhabitants, besides the garrison. The environs are pleasant and fruitful, and the castle, with Hamlet's Garden, as it is called, is visited by most English travellers who arrive at Elsineur. It is in long. 12. 35. 19. E. and lat. 56. 1. 40. N.

ELSNAPPEN, a small seaport of Sweden, in Westmanland. It is on the side of the Baltic, and is capable of admitting ships of war. Thirty-two miles east-north-east of Nykioping.

ELTHAM, a market-town of the county of Kent, in the hundred of Blackheath, eight miles from London. The market is held on Monday. It is remarkable for the manor-house called King John's Palace, formerly a royal residence; and for a modern building on Shooter's Hill, erected by Commodore James, to celebrate his capture of a similar fortress called Savendroog, belonging to Angria, a pirate on the coast of Bombay, in India. The population amounted in 1801 to 1627, in 1811 to 1813, in 1821 to 1883, and in 1831 to 2129.

ELTMANN, a bailiwick of the circle of the Lower Maine, in the kingdom of Bavaria, extending over forty-four square miles. It contains, besides the capital, thirteen villages and 3039 inhabitants. The capital, of the same name, is situated on the river Zeil, and contains 1010 inhabitants.

ELVAS, a town of Portugal, in the province of Alemtejo. It is well fortified, and may be considered as one of the keys of the kingdom to the south, on the side of Spain; and it is one of the fortresses opposed to the city of Badajos.

ELY, a city of Cambridgeshire, the chief place of a division of that county distinguished as the Isle of Ely, having a distinct jurisdiction, the chief justice and other magistrates of which are nominated by the bishop. The city, though elevated somewhat above the surrounding country, is considered as unhealthy, from the marshy soil which surrounds it. It is not a well-built place, and consists chiefly of one street. The cathedral is an object of attraction as the work of several ages, displaying a mixture of the Anglo-Norman and English styles of architecture. It is upwards of 400 feet in length, and has a tower at the west end 270 feet in height. There are, besides, two parish churches. The bishopric is one of the most valuable in England, both on account of its income and its patronage. It is the only city which sends no members to the House of Commons. The land around it is highly fertile; much of it is appropriated by market-gardeners, and supplies the neighbourhood as far as Cambridge with culinary vegetables. The market is held on Saturday. It is sixty-six miles from London, and fourteen from Cambridge. The population amounted in 1801 to 3713, in 1811 to 4249, in 1821 to 5079, and in 1831 to 6189.

ELYSIUM, the place which, according to the ancient poets, the souls of the blessed inhabited. By Homer it was placed in the vicinity of Oceanus, and on the extreme confines of the earth. Here Nature produced her most delicious fruits without assistance from the hand of man. No winter storm ever obscured the brilliancy of the atmosphere; but cooling zephyrs refreshed the air, and wafted on their wings the most delightful perfumes. Such was the abode destined by Jupiter for his son-in-law Menelaus. It is curious to observe the various changes of position in respect to these Elysian Fields, as a more intimate acquaintance with the geography of different countries successively dispelled the erroneous impressions made by the foolish statements of travellers. The Greeks in the earlier ages placed them in the district of Thesprotia, where they also found the Acheron, Cocytus, and Avernus; and it was to this elysium that Homer tells us Mercury conducted the souls of the suitors of Penelope, after they had been killed by Ulysses. But they afterwards transported the Elysian Fields and Avernus to the vicinity of Baia in Campania.

> Largior hic campos æther et lumine vestit
> Purpureo; solemque suum, sua sidera norunt.

And it was not till later times that they thought of fixing these imaginary abodes at the extremity of Iberia, where they found the Lethe, "that slow and silent stream, the river of oblivion," which is now called *Guadalete*, as well as another of the same name in Lusitania.

ELZEVIRS, celebrated printers at Amsterdam and Leyden, who greatly adorned the republic of letters with many beautiful editions of the best authors of antiquity. They were five in number, namely, Louis, Bonaventure, Abraham, Lewis, and Daniel. Louis began to be famous at Leyden in 1595, and was remarkable for being the first who observed the distinction between the *v* consonant and *u* vowel, which had been recommended by Ramus and other writers long before, but never regarded. Daniel died in 1680 or 1681; and though he left children who carried on the business, he nevertheless passes for the last of his family who excelled in printing.

EMANATION, the act of flowing or proceeding from some source or origin. Such is the emanation of light from the sun; that of effluvia from odorous or fragrant bodies; of wisdom from God, and so on. The word is formed of the Latin *e*, out of, and *manare*, to flow or stream. Emanation is also used to signify that which proceeds, as well as the act of proceeding. The power given to a judge is an emanation from the royal authority; the reasonable soul is an emanation from the divinity.

EMANCIPATION, in the Roman law, the setting free of a son from the subjection of a father; so that whatever moveables he acquires belong in property to him, and not to his father, as before emancipation.

By emancipation the son was put in a capacity of managing his own affairs, and of marrying without his father's consent, although a minor. Emancipation differed from manumission, as the latter was the act of a master in favour of a slave, whereas the former was that of a father in favour of his son.

There were two kinds of emancipation; the one tacit, which was by the son's being promoted to some dignity, by his coming of age, or by his marrying, in all which cases he became his own master of course; the other express, where the father declared before a judge that he emancipated his son. In performing this act, the father executed an imaginary sale of his son to another person, who was called *pater fiduciarius*, or father in trust; from whom the son was immediately purchased by the natural father, who thereafter manumitted him before the judge by a verbal declaration.

EMATHIA, the ancient name of Macedonia, which was afterwards restricted to the country in the immediate vicinity of Edessa. This district was originally a part of Pæonia, and contained the extensive and fertile plains on the banks of the rivers Axius and Erigonus. (Polyb. *Frag.* xxiv. 8; Liv. x. 4, 11.) In the time of the Romans Emathia must have extended much farther to the south, as Ptolemy includes in this district the cities of Berrhœa and Pella.

EMBALMING is the opening of a dead body, taking out the intestines, and filling the space with odoriferous and desiccative drugs and spices, in order to prevent putrefaction and decomposition. The Egyptians excelled all other nations in the art of preserving bodies from corruption; for some that were embalmed several thousand years ago remain whole to this day, and are often brought as curiosities into other countries. Their manner of embalming was this: They scooped the brain with an iron scoop out at the nostrils, and threw in medicaments to fill up the vacuum; they also took out the entrails, and having filled the body with myrrh, cassia, and other spices (except frankincense), proper to dry up the humours, they pickled it in nitre, where it lay soaking for seventy days. The body was then wrapped up in bandages of fine linen and gums, to make it stick like glue; and so was delivered to the kindred of the deceased, entire in all its features, the very hairs of the eyelids being preserved. They used to keep the bodies of their ancestors, thus embalmed, in apartments magnificently adorned, and took great pleasure in beholding them, alive as it were, without any change in their size, features, or complexion. The Egyptians also embalmed birds and other animals. The prices for embalming were different; the highest was a talent, the next twenty minæ, and so on, decreasing to a very small matter. But they who had not wherewithal to answer this expense contented themselves with infusing, by means of a syringe, through the fundament, a certain liquor extracted from the cedar; and, leaving it there, wrapped up the body in salt of nitre. The oil thus infused preyed upon the intestines, so that when they took it out, the intestines came away with it, dried, and not in the least putrefied; and the body being inclosed in nitre, grew dry, nothing remaining besides the skin glued upon the bones. The process of embalming is described both by Herodotus and Diodorus. The former, who is unquestionably the better authority, says (book ii. sect. 85), "This service is performed by persons appointed to exercise the art as their business. When a dead body is brought to them, they show their patterns of mummies in wood, imitated by sculpture; and the most elaborate of these they say belongs to the character of one (Osiris), whose name I do not think it pious to mention on such an occasion; the second that they show is less costly; the third, the cheapest of all: and having shown these, they inquire in which way the service shall be performed; upon which the parties make their agreement, and the body is left for preparation. The interior soft parts being removed both from the head and from the trunk, the cavities are washed with palm wine and fragrant gums, and partly filled up with myrrh and cassia, and other spices; the whole is then steeped in a solution of soda for seventy days, which is the longest time permitted; and then, having been washed, the body is rolled up with bandages of cotton cloth, being first smeared with gum instead of glue. The relations then, receiving the body, procure a wooden case for it in a human shape, and inclose the dead body in it; and when thus inclosed, they treasure it up in an appropriate building or apartment, placing it upright against the wall. And this is the most expensive mode of preparation. For those who prefer the middle class, in order to avoid expense, the process is simplified by omitting the actual removal of the interior parts, and introducing a corrosive liquid to melt them down; the soda consumes the flesh, so that skin and bone only are left when the body is returned to the friends. The third and simplest process is merely to cleanse the body well, within and without, by means of some vegetable decoctions, and to keep it in the alkaline solution for the seventy days, without farther precautions." Embalming appears also to have been performed by filling the cavities of the thorax and abdomen, after the intestines were removed, with a species of pitch which was poured into the trunk of the body in a liquid state, through an aperture made on purpose in the right side, whilst the head was treated in a similar manner. See the article MUMMY.

EMBANKMENT a mound or wall of earth, or other materials, used as a defence against the inundations of rivers, or the extraordinary flux of the sea.

The great value of alluvial soil to the agriculturist no doubt gave rise to the invention of banks or other barriers, to protect such soils from the overflowing of their accompanying rivers. The civilized nations of the highest antiquity were chiefly inhabitants of valleys and alluvial plains, the soil, moisture, and warmth of which, by enlarging the parts, and ameliorating the fruits of the vegetable kingdom, afforded to man better nourishment at less labour than could be obtained in hilly districts. The country of Paradise and around Babylon was flat, and the soil a saponaceous clay, occasionally overflown by the Euphrates. The inhabited part of Egypt was also entirely of this description. Historians inform us that embankments were first used by the Babylonians and Egyptians, very little by the Greeks, and a good deal by the Romans, who embanked the Tiber near Rome, and the Po for many stadia from its embouchure. The latter is perhaps one of the most singular cases of embankment in the world.

The oldest embankment in England is that of Romney Marsh, as to the origin of which Dugdale remarks, "that there is no testimony left to us from any record or historian." (*History of Embanking and Draining.*) It is conjectured to have been the work of the Romans, as well as the banks on each side of the Thames for several miles above London, which protect from floods and spring tides several thousand acres of the richest garden ground in the neighbourhood of the metropolis.

The commencement of modern embankments in England took place about the middle of the seventeenth century, under Cromwell. In the space of a few years previously to 1651, about 425,000 acres of fens, morasses, or overflown muddy lands, were recovered in Lincolnshire, Cambridgeshire, Hampshire, and Kent, and let at from 2s. 6d. to 30s. an acre. (Harte's *Essays*, p. 54, 2d edit.) Vermuyden, a Fleming by birth, and a colonel of horse under Cromwell, who had served in Germany during the thirty years' war, was the principal undertaker of these works. The works of this sort constructed in our own times will be found described in the *Agricultural Reports* of the maritime counties, especially of Lincolnshire, by Arthur Young.

Previously to entering on the detail of the different descriptions of banks for the purpose of embanking, we shall here observe, that the pressure of still water against the sides of the vessel containing it being as its depth, it follows that a bank of any material whatever, impervious to water, whose section is a right-angled triangle, and the height of whose perpendicular side is equal to that of the water it is to dam in, will balance or resist this water, whatever may be the breadth of the surface of the latter; and therefore, that as far as width or extent is concerned, it is just as easy to exclude the Atlantic Ocean as a lake or a river of a few yards in width.

The earthen wall.

1. The Earthen Wall (Plate CCXVIII. fig. 1,) is the simplest description of embankment, and is frequently erected by temporary occupiers of lands, on the general principle of inclosing and subdividing, which is sometimes made a condition of tenure between the landlord and tenant. This wall applies to lands occasionally but rarely overflown or inundated, and is set out in a direction generally parallel to the river or shore. Its base is commenced on the surface from two to five feet wide, regularly built of turf on the outsides, with the grassy sides underneath. The middle of the wall is filled up with loose earth. The wall is carried up with the sides bevelled towards the centre, so as to finish in a width of one foot or eighteen inches at five or six feet in height. In the inside of such walls, and at the distance of three or four feet, a small open drain is formed, as well to collect the surface-water of the grounds within, as that which in time of floods will necessarily oose through a wall of this construction. The water so collected is let through the wall by tubes, or tunnels of boards, with a valve opening outwards on their exterior extremity. Such a tube and valve is represented by fig. 2. When the flow of water from without approaches, it shuts the valve, which remains in this state till the flood subsides, when, the height of the water within being greater than that without, it presses open the valve and escapes. Walls and valves of this kind were erected about the year 1800, on the estate of the Earl of Galloway near Wigton, by Mr Hannah, tenant for life of Cue farm, and by Mr Hutchinson, tenant for thirty years of Mersehead farm, on the Solway Frith. (*Farmer's Magazine.*) They are common enough in the drier parts of the fenny districts of Lincolnshire and Cambridgeshire; and in Caernarvonshire 1800 acres were in 1804 completely protected in this way on the estate of Tre Madoc, by the proprietor, who has since made greater efforts in embanking, to be afterwards described.

The earthen mound.

2. The Earthen Mound (fig. 3) is the most general description of embankment, and, as it is executed at considerable expense, is only undertaken by such as have a permanent interest in the soil. This barrier applies to sea lands overflown by every spring tide, and to alluvial plains inundated by every flood. It is set out in a direction parallel to the shore and to the general turns of the river, but not to its minute windings; and it is placed farther from or nearer to the latter, according to the quantity of water in time of floods, the rapidity of the current from the declivity of the bed, the straight course of the stream, and the intended height of the bank. The two sides of such a mound are generally formed in different slopes. That towards the land is always the most abrupt, but can never be secure if more so than 45°; that towards the water varies from 45° to 15°; the power of the bank to resist the weight of the water, as well as to break its force when in motion, being inversely as its steepness. The power of water to lessen the gravity of bodies, or, in other words, to loosen the surfaces over which they flow or stand, is also lessened in a ratio somewhat similar.

The formation of such a mound consists merely in taking earth from the general surface of the ground to be protected, or from a collateral excavation, distant at least the width of the mound from its base line, and heaping it up in the desired form. The surface is then in general cases covered with turf, well rolled in order to bind it to the loose earth. The earth of such mounds is generally wheeled by barrows; but sometimes it is led by carts placed on a wooden roller instead of wheels, which, with the treading of the horses, serves in some degree to consolidate the bank.

The excavation within serves the same purpose as the open drain in the *earthen wall*, and similarly constructed sluices or valves are introduced on a larger scale. Sometimes also the interior water is drawn off by windmills, and thrown over the mound into the river. This is very common in Huntingdonshire, and might be greatly improved on by employing steam-engines for entire districts, one of which, of a ten-horse power, would do the work of twenty mills, and this in calm weather, when the latter cannot move.

Embankments of this description are the most universal of any, and their sections vary from a scalene triangle of ten feet in base and three feet in height, as on the Forth near Stirling, and the Thames at Fulham, to a base of 100 feet and a height of ten feet, as on the great bank of the Ouse, near Wisbeach. The great rivers of Germany and Holland are embanked in this way when so far from the sea as to be out of the reach of the tide; as the Vistula at Marienwerder, the banks of which, near Dantzic, are above fifteen feet in height; the Oder, the Elbe, &c. All these banks are closely covered in every part with a grassy surface, and sometimes ornamented with rows of trees.

But near the sea, where such banks are washed by every tide when the course of the wind is towards the shore, and by all land floods and spring tides, grass is only to be found on and near their summits. The rest of the bank is bare, and to preserve it from the action of waves, currents, and the stones, pieces of wood, and other foreign matters which they carry with them, the surface is covered with gravel, reeds, or straw, kept down by pieces of wood, faggots, wicker hurdles, nets of straw-ropes, or any other contrivance, according to the situation, to prevent the washing away of the bank. It is common to attribute to these coverings the power of breaking the force of the waves; but this power depends, as we have already stated, on the slope of the bank and its smoothness; and the use of the surface covering, and of the constant attention required to remove all obstacles which may be left on it by floods and tides, is to prevent the loosening power of the water from wearing it into holes. For this purpose, a sheet of canvass or straw-netting is as good whilst it lasts as a covering of plate-iron or stone pavement.

All banks whatever require to be constantly watched in time of floods or spring-tides, in order to remove every object, excepting sand or mud, which may be left by the water. Such objects, put in motion by the water, in a short time wear out large holes. These holes, presenting abrupt points to the stream, act as obstructions, soon become much larger, and, if not immediately filled up, turfed over, and the turfs pinned down, or the new turfs rendered by some other means not easily softened and raised up by the water, will end in a breach of the bank. A similar effect is produced by a surface formed of unequal degrees of hardness and durability. The banks of this description in Holland, at Cuxhaven, and along the coast of Lincolnshire, are regularly watched throughout the year; the surface protection is renewed whenever it goes out of repair, as is the body of the bank in the summer season.

Varieties of the mound.

Mound with puddle-wall.—It generally happens that the earth of such banks is alluvial, and their foundation of the same description; but there are some cases where the basis is sand, silt, or gravel, or a mud or black earth, as in some parts of Cambridgeshire and Lincolnshire, which does not easily become so compact. Here it is common, before beginning the bank, to bring up what is called a puddle-ditch, or section of clay, in the centre of the highest part of the mound in the direction of its length, and of three or five feet wide, according to the depth of the silt and the intended height of the bank. When the clay of this puddle-ditch is well worked, either by men's feet or clay rammers, the bank will be perfectly impervious to water, and, if against a mild stream or shore, need not contain such an accumulation of earth as where the imperviousness of the bank to water depends chiefly on the mass of materials. An important point to attend to in this variety of mound is, to found the section or wall of clay so deep as to be in contact with a stratum, either by induration or its argillaceous nature impervious to water.

Mounds with reversed slopes (fig. 4).—In some cases of embanking rivers, as where they pass through parks, it is desirable to conceal as much as possible the appearance of a bank from the protected grounds, less able to break the force of waves. Here the mound is simply reversed, the steepest side being placed next the water. It is proper to observe, that such banks are not so strong by the difference of the weight of the triangle of water which would rest on the prolonged slope were it placed next the river, and are more liable to be deranged in surface in proportion to the difference of the slopes.

Mound faced with stones.—This is the same species of mound, with a slope next the water of forty-five or fifty degrees, paved or causewayed with stones or timber. In Holland this pavement or causeway is often formed of planking or bricks; but in England generally with stones, and the mortar used is either some cement which will set under water, or, what is better, plants of moss firmly rammed between them. The objections to such banks are their expense, and their liability to be undermined invisibly by the admission of the water through crevices. They are, therefore, chiefly used where there is little room, or where it is desirable to narrow and deepen the course of a river.

Mound protected by a wicker hedge.—This is a Dutch practice, and, where appearance is no object, has the advantage of not requiring watching. Wicker-work, however, subjected to the strain of waves, will be obviously less durable than where it lies flat on the ground, and can only decay chemically. This wicker hedge is sometimes a series of hurdles supported by posts and struts; but generally in Britain it is a dead hedge or row of stalks wattled or wrought with bushes presenting their spray to the sea or river. Besides placing such a hedge before a bank, others are sometimes placed in parallel rows on its surface; the object of which is to entrap sand, shells, and sea-weeds, to increase the mass of mound, or to collect shells for the purpose of carrying away as manure.

The sea wall (fig. 5) is an embankment formed to protect abrupt and earthy shores or banks of rivers, and consists of a wall, varying in thickness, and in the inclination of its surface, according to the required height and other circumstances. Belidor, in his *Traité de Hydraulique*, has given the exact curve which the section of such a wall ought to have in order to resist loose earth, and which is somewhat greater than what we have given in the figure referred to, where the earth behind the wall is supposed to be chiefly firm. Some fine examples of such walls, for other purposes, occur in the CALEDONIAN CANAL; and perhaps the finest in the world are the granite walls which embank the Neva at Petersburg, the construction of which may serve as an example of a river case with a foundation of soft bog earth. A space of the river, say 100 feet long, and twenty wide along shore, being inclosed by a double row of piles, and filled in with loam in the usual way, the water is pumped out, and the ground excavated about ten feet deeper than the margin of the bed of the river. Poles are then inserted nearly as close as they can be put in, and driven to their full length. When finished, this foundation occupies a breadth of from twelve to eighteen feet, generally fifteen. The tops of the piles are now cut level, and covered with planks, and on this is raised a mass of brick-work for five or six feet, sloping on both sides as it ascends towards the centre line of the wall. In the course of rising six or seven feet, it is narrowed to five feet, and is within five feet of the bed of the margin of the river. Here the granite facing begins in immense blocks, and is continued at a slope of fifteen degrees from the perpendicular, till it reaches the surface of the intended pathway. Here the wall from three feet is narrowed to an upright parapet eighteen inches wide; and at four feet of height it is finished in a projecting coping of Finnish granite. The voids on each side of the wall are now filled with earth, the pavement on the land side (generally narrow) completed, and the piles removed, and another length taken in to repeat the operation.

There is another mode, adopted in Petersburg, of building under water by driving the piles and cutting them over level with a machine, and then sinking caissons of brick-work. This mode, however, is unsuitable for sea walls in general, which ought to be founded as deep as possible, and at all events under the bed of the water. The motion of the Neva is so slow as hardly to render this worth attending to.

In Britain, such walls are fortunately rare; for in proportion as it is agreeable and flattering to self-love to protect or gain lands never before cultivated, it must be mortifying to be obliged to protect such as have long been subjected to agriculture, and where success can only be said to have a negative advantage.

Embankments for fixing drifting-sands, shells, or mud.—In several tracts of coast, the sea at ordinary tides barely covers a surface of sand, and these sands in dry weather, during high winds, are drifted and blown about in all directions. Great part of the north shores of the Solway Frith, of Lancaster Bay, and of the coast of Norfolk, is of this description. Mr Young, in his *Farmer's Letters*, informs us, that a considerable part of the county of Norfolk was drift-sand, even as far inland as Brandon in Suffolk, before the introduction of the turnip culture; and Harte (*Essay I.*) states, that some of what is now the richest land in Holland was, about the middle of the sixteenth century, of this description. The suggestion of any mode, therefore, by which, at a moderate expense, such tracts could be fixed and covered with vegetation, must be deemed worthy of a place in this article.

The mode which nature herself employs is as follows: After the tides and wind have raised a marginal strip of sand as high as high-water mark, it becomes by degrees covered with vegetation, and chiefly by the *elymus arenarius*, *triticum junceum*, various species of *Juncus*, and sometimes by the *galium verum*. With the exception of the first of these plants (the leaves and stalks of which are manufactured into mats and ropes in Anglesea, and the grain of which is ground and used as meal in Ireland), they are of no other use than fixing the sands, which, being composed in great part of the debris of shells, expand as they decay, and contribute to raise the surface still higher, when the fibrous roots of good grasses soon destroy the others.

To assist nature in fixing drift-sands, it is only necessary to transplant the *elymus*, which is to be had in abundance in almost every sandy coast in Britain; and as it would be liable to be blown away with the sands if merely inserted in the common way, it seems advisable to tie the plants to the upper ends of *willow* or *elder* rods, of two or three feet in length, and to insert these in the sand, by which means there is the double chance of the grass growing, and the truncheon taking root. The elder will grow exposed to the sea breeze, and no plant throws out so many and such vigorous roots in proportion to its shoots.

The mode by which sands were fixed in Holland was by the formation of wicker work embankments, and by sticking in the sands branches of trees, bushes, furze, &c. in all directions. These obstructed the motion of the sands, and collected masses of sand, shells or mud, and sea-weeds around them, which were immediately planted with some description of creeping grass; or, what was more frequent, covered with a thin coating of clay, or alluvial earth, and sown with clover.

Though the most certain and least expensive mode of gaining such lands be undoubtedly that of seconding the efforts of nature, by inserting bushes, and planting the *elymus* in this way, yet it may sometimes be desirable to make a grand effort to protect an extensive surface, by forming a bank of branches, which might in a single or in several tides be filled with sand and shells. It is evident that such a bank might be constructed in various ways; but that which would be most certain of remaining firm, and effecting the purpose, would be one regularly constructed of framed timber, the section of which would resemble a trussed roof; each truss being joined in the direction of the bank by rafters, and the whole inside and surface stuck full of branches. To retain it firm, piles would require to be driven into the sand, to the upper parts of which would be attached the trusses. The height of such a barrier would require to be several feet above that of the highest spring-tides; and the more its width at base exceeded the proportion of that of an equilateral triangle the better.

A more economical mode, and one, therefore, suited to a less extensive scale of operation, is to intersect a sandy shore in all directions with common dead or wicker-work hedges, formed by first driving a row of stakes six or eight feet into the ground, leaving their tops three or four feet above it, and then weaving among these stakes branches of trees or the tops of hedges. The Dutch are said to weave straw ropes, and thereby to collect mud in the manner of *warping*. This mode being little expensive, seems to deserve a trial in favourable situations; and, in so doing, it must not be forgotten that much depends on the immediate management of the surface after it is in some degree fixed. In an extensive trial of this sort made on the west coast of Scotland, under an English gentleman, seeds and roots were baked in a mixture of loam and dung in the gravel, and then formed into masses, and scattered over a sandy surface. These, from their weight, will not, it is thought, be moved by the water or the wind; but becoming more or less covered with sand, the mass will be kept moist, and the seeds and roots will grow, and, fixing themselves in the soil, will in time cover the surface with verdure.

Embankments for straightening the course of rivers.—Where a river in a fertile valley is very circuitous in its course, land may be gained, and a more rapid efflux of the water produced, by straightening its course. The best plan in general for effecting this is, to find an entirely new bed or course for the river; otherwise, when it passes alternately through new soil and through a part of its old bed, its action on surfaces which are so different in regard to induration ends, if great care be not taken, in holes and gulleys in the new bank, which require to be constantly filled up with loose stones thrown in, and left to be fixed by the pressure and motion of the water.

The embankment used in straightening the course of rivers is almost always the mound with a clay wall in the centre, varying in width according to the depth of the different parts of the old bed of the river which it has to intersect. The materials for these banks are obtained from excavations for the new bed.

The pier called the *protecting pier* is to be considered as a species of embankment the object of which is to prevent the increase of partial breaches made in the banks of rivers, by accidental obstructions during floods. A tree or branch carried down by a stream, and deposited or accidentally fixed or retained in its banks, will repel that part of the stream which strikes against it, and the impulse, counteracted more or less by the general current, will direct a substream against the opposite bank. The effect of this continual action against one point of the opposite bank is to wear out a hole or breach, and the protecting pier is placed so as to receive the impulse of the substream, and reverberate it to the middle of the general stream. If this pier be not placed very obliquely to the substream, as well as to the general stream, it will prove injurious to the opposite bank, by directing a subcurrent there as great as the first; and, indeed, it is next to impossible to avoid this; so much so, that Mr Smeaton, in every instance in which he was consulted in cases of this sort, recommended removing the obstacle where that could be done, and then throwing loose stones into the breach. A perfect bed of a river would be a perfect half cylinder, and therefore we are decidedly of opinion that Mr Smeaton's mode is the best, as tending to maintain as much as possible this form. Mr Marshal (*Treatise on Landed Property*) has treated on piers of this description at considerable length; but a very little reflection will show that they are more likely to increase than to remedy the evil they are intended to cure. We have seen the injurious effects of such piers on the Tay and the Dee; and on a part of the Jed near Crailing they are so numerous that the stream is, to use a familiar phrase, bandied about like a football from one shore to the other; behind every pier an eddy is formed, and, if the stream does not strike it exactly, a breach in the bank. Many of these piers have in consequence been taken down.

The use of such piers can only be justified where the obstruction, from ill neighbourhood or some such cause, cannot be removed from the opposite bank; or where, as is sometimes the case, it arises from an island of sand or gravel thrown out by the river near its middle, and which, however absurd it may appear, the interested parties cannot agree as to who may remove it. The case of buildings also being in danger may justify such a pier for immediate protection; but if such breaches are taken in time, a few loads of loose stones will effect a remedy without the risk of incurring or occasioning a greater evil.

Such piers are frequently constructed of wicker work; either a mere wicker hedge projecting into the water, as is common where the rivers are of slow motion, as in England, and particularly on the Thames, Tame, and Severn; or a case of wicker work filled with stones, as is common where the motion is rapid, as in Scotland, and particularly on the Esk, Tweed, Tay, and Clyde.

Embankments to serve as roads are generally mounds without clay walls, carried through countries liable to be overflown, without reference to protecting any part from water, through lakes or marshes, or across straits of the sea. The earth in such mounds is generally allowed to take its own slope on both sides, which is commonly from forty to forty-five degrees, and the width at top is regulated by that of the intended road. The materials, when the mound is formed in a country merely liable to be overflown, as in many parts of Lincolnshire and Huntingdonshire, are excavated from ditches, or taken from the surface on each side of the mound. In Holland the roads formed on such mounds are bounded by rows of trees; a practice which it is to be regretted has not been more attended to in England, where accidents not unfrequently happen in the night, and particularly on the Boston and Wisebeach roads, both of which are formed in great part on such mounds, unprotected by hedges, rails, or trees. In passing through part of a lake, or strait, or marsh, the earth must of course be taken from the firm ground on the shores; and here the ground being generally soft below, the first operation is to lay a foundation three or four feet thick, of branches or faggots of copsewood, in order that the mound may sink in a body. The next thing, the direction of the mound being marked out by a line of poles placed along its centre, is to begin at one end, and wheel or cart on earth, throwing it down in the direction of the bank, raising it to its proper height and width, leaving the slopes at the sides to adjust themselves, either by the gravity of the material alone, or jointly with the loosening and spreading operation of the water.

The noblest attempt of this sort ever made in Britain was that of W. A. Madocks, Esq. in order to unite the counties of Merioneth and Cardigan by a mound across an estuary and embouchure of the Glasslyn, two miles wide. Mr Madocks had, in 1802, succeeded in protecting from spring tides, by a wall or bank of the first species, 1800 acres of good alluvial soil, which he let at from 30s. to 50s. per acre; and his enterprising spirit induced him to contemplate the idea of gaining the whole bay or mouth of the stream, extending to nearly 4000 acres of alluvial and sandy earth, overflowed in great part by every tide. Besides the mere gaining of the land, this patriotic improver had another object in view; that of uniting two maritime points in two counties which at that time were separated by a day's journey; and, by effecting this, he would at the same time have rendered practicable a new line of road from Worcester along the top of this embankment, through a creation of his own, called the town of Tre Madoc, to the newly formed harbour of Porthdynlleyn, by which forty miles would have been saved to the public between Dublin and London, and fifty between Dublin and Bath.

After consulting various engineers, the first operation was begun in 1807, and consisted in forming an immense bridge of flood-gates in the solid rock of the shore, as such a bridge and gates could not be formed in any part of the mound. The use of this was to admit the exit of the river. This done, the mound was commenced from both shores, and rocky, sandy, and clayey materials thrown down in the direction of the mound, and left to take their own slope. The greater part of these materials consisted of argillaceous rock broken into small pieces, which being mixed with clay, the mound would have been of the strongest texture. As the work proceeded, an iron railroad was laid along the top of it, and extended to the quarries and excavations, by which means much labour was saved. In the course of three years the work was brought within fifty yards of meeting in the middle, but it was found extremely difficult to close it, from the rapidity of the influx and reflux of the tide. This difficulty, however, would have been overcome, and the proposed improvement effected at little more than the estimated cost, L.20,000, had not the various and extensive projects in which the proprietor was at that time engaged led him into pecuniary difficulties, which put an end to the undertaking, and, as is usual in such cases, called forth popular clamour against the plan. It is but justice, however, to those concerned to state, that the very plan now put in execution was contemplated above a century ago by Sir Hugh Middleton, who then wrote to a friend, that if he were not so deeply engaged in the scheme of bringing water to London, he should certainly engage in it.

Very little has been written on the subject of embankments, as a separate branch of art, by British authors. Dugdale's work is entirely historical and topographical; but the writings of Smeaton, Young, Gregory, and others, contain the general principles on which is founded the art of embanking, and every other operation connected with water.

EMBARCADERO, in *Commerce*, a Spanish term, much used along the coasts of America. It signifies a place which serves some other considerable city farther inland for a port or place of shipping, that is, of embarking and disembarking commodities.

EMBARGO, in *Commerce*, an arrest on ships or merchandise by public authority, or a prohibition of state, commonly on foreign ships, in time of war, to prevent their going out of port, or coming in, and sometimes both, for a limited time.

EMBER WEEKS are those in which the *ember* or *embring days* fall.

In the laws of King Alfred and those of Canute, these days are called *ymbren*, that is, circular days, from which the word was probably corrupted into *ember days*. By the canonists they are called *quatuor anni tempora*, the four cardinal seasons on which the circle of the year turns; and hence Henshaw takes the word to have been formed by corruption from *tempora*. The ember days are the Wednesday, Friday, and Saturday, after Quadragesima Sunday, after Whitsunday, after Holy-rood day in September, and after St Lucia's day in December; which four times answer well enough to the four quarters of the year, spring, summer, autumn, and winter. Mr Somner thinks they were originally fasts, instituted in order to crave God's blessing on the fruits of the earth; agreeably to which, Skinner supposes the word *ember* taken from the ashes, *embers*, then strewed on the head. These ember weeks are now chiefly taken notice of on account of the ordination of priests and deacons; because the canon appoints the Sundays next succeeding the ember weeks for the solemn times of ordination; though the bishops, if they please, may ordain on any Sunday or holiday.

EMBLEM, a kind of painted enigma, which represents some obvious history, with reflections underneath, and instructs us in some moral truth or other matter of knowledge. Such is that very significant image of Scævola holding his hand in the fire; with the words, *Agere et pati fortiter Romanum est*, to do and to suffer courageously is Roman. The word is pure Greek, formed of the verb εμβαλλειν, *to cast in* or *insert*. Suetonius relates that Tiberius caused the word to be erased from the decree of the Roman senate, because borrowed from another language. The emblem is somewhat plainer and more obvious than the enigma. Gale defines emblem an ingenious picture, representing one thing to the eye, and another to the understanding.

The Greeks also gave the name *emblems*, εμβληματα, to inlaid or mosaic works, and even to all kinds of ornaments of vases, moveables, garments, and the like. The Latins also used *emblema* in the same sense. Accordingly, Cicero, reproaching Verres with the statues and finely wrought works he had plundered from the Sicilians, calls the ornaments fixed thereto, and which on occasion might be separated from them, *emblemata*; and, further, the Latin authors frequently compare the figures and ornaments of discourse to these *emblemata*. Thus, an ancient Latin poet praising an orator, says, that all his words were ranged like the pieces in mosaic:

> Quam lepide λεξεις compostæ, ut tesserulæ omnes,
> Arte pavimento, atque *emblemate* vermiculato.

With us emblem ordinarily signifies no more than a painting, bas-relief, or other representation, intended to convey some moral or political instruction.

What distinguishes an emblem from a device is, that the words of an emblem have a full and complete sense of themselves; whereas those of a device are significative only with reference to some particular person or thing. A device, in short, is a symbol appropriated to some person, or that expresses something which concerns him particularly; whereas an emblem is a symbol that regards all the world alike. These differences will be more apparent from comparing the emblem above quoted, with the device of a candle lighted, and the words *Juvando consumor*, I am wasted in doing good.

EMBOLISMUS, Εμβολισμος, in *Chronology*, signifies *intercalation*. The word is formed from εμβαλλειν, *to insert*. As the Greeks made use of the lunar year, which is only 354 days, in order to bring it to the solar, which is 365 days, they had every two or three years an embolism, that is, they added a thirteenth lunar month every two or three years, which additional month they called *embolimæus*, εμβολιμαιος, because inserted or intercalated.

EMBOSSING, or IMBOSSING, in *Architecture* and *Sculpture*, the forming or fashioning of works in relief, whether cut with a chisel or otherwise. Embossing is a kind of sculpture in which the figure stands out from the plane on which it is cut; and according as the figures are more or less prominent, they are said to be in alto, mezzo, or basso-relievo; or high, intermediate, or low relief.

EMBRASURE, in *Architecture*, an enlargement made of the aperture of a door or window on the inside of the wall, the use of which is to give greater play for the opening of the door or casement, or to admit more light.

EMBROIDERY, a work in gold, or silver, or silk thread, wrought by the needle upon cloth, stuffs, or muslin, into various figures. In embroidering stuffs, the work is performed in a kind of loom, because the more the piece is stretched the easier it is worked. As to muslin, it is spread upon a pattern ready designed, and sometimes, before it is stretched upon the pattern, it is starched, to make it more easy to be handled. Embroidery on the loom is less tedious than the other, in which, whilst the flowers are worked, all the threads of the muslin, both lengthwise and breadthwise, must be continually counted; but, on the other hand, this last is much richer in points, and susceptible of greater variety. Cloths too much milled are scarcely susceptible of this ornament, and in effect we seldom see them embroidered.

There are several kinds of embroidery, viz. 1. Embroidery on the stamp, where the figures are raised and rounded, having cotton or parchment put under them to support them. 2. Low embroidery, where the gold and silver lie low upon the sketch, and are stitched with silk of the same colour. 3. Guimped embroidery. This is performed either in gold or silver. A sketch is first made upon the cloth, then put on cut vellum, and afterwards sewed on the gold and silver with silk thread; and on this kind of embroidery are often put gold and silver cord, tinsel, and spangles. 4. Embroidery on both sides, that which appears on both sides of the stuff. 5. Plain embroidery, or where the figures are flat and even, without cords, spangles, or other ornaments.

EMBRUN, an arrondissement of the department of the Upper Alps, in France, extending over 583 square miles. It is divided into five cantons and thirty-six communes, and contains 28,628 inhabitants. The capital, of the same name, is situated on the top of a steep rock, at the foot of which flows the river Durance. It has a cathedral, an episcopal palace, and a large prison; and contains 700 houses and 3133 inhabitants. Long. 6. 20. E. Lat. 44. 34. N.

EMBRYO, in *Physiology*, the rudiments of an animal in the uterus, before the several members are distinctly formed, after which period it is denominated a *fœtus*.

EMDEN, a bailiwick of the province of West Friesland, in the kingdom of Hanover, extending over eighty-one square miles, and containing a city, a market-town, and thirty parishes, with 18,925 inhabitants. It is mostly marsh land, and is only preserved from inundation by powerful dikes or embankments, which are maintained at a vast expense; but the land is highly fertile, and more than adequate to defray these charges. It is especially productive in oats, and in butter and cheese. The capital, from which it takes its name, is situated on the river Ems, but a mile and a half distant, and is surrounded with walls, which, however, are indefensible. It contains four reformed, one Lutheran, and one Catholic church, a Menonite chapel, and a Jews' synagogue, with 1808 houses, and 12,100 inhabitants. It is a place of great trade, as well for the export of oats, butter, cheese, and bacon, as for the herring fishery; and there are many breweries and distilleries, some ship-building, and other occupations of industry. It is, besides, the seat of government for East Friesland. Long. 7. 5. 35. E. Lat. 53. 22. 8. N.

EMERALD, *Smaragdus*, *Schmaragd*, *Eméraude verte*. In mineralogy this includes two subspecies; the emerald properly so called, or the precious emerald, comprehending the transparent and beautiful green-coloured varieties, and the beryl, which has already been described under its appropriate head.

The emerald always occurs crystallized, its most common form being that of a regular six-sided prism, occasionally modified by truncations on the terminal edges. It is in general well characterized by that pure and lively green colour which has hence received the name of *emerald green;* its hue, however, varies somewhat, inclining at times to verdigris or grass green, and frequently becoming rather pale. This fine colour is occasioned by the presence of a minute portion of the oxide of chrome, to which, indeed, may be attributed the principal distinction between emerald and the beryl; the mountain-green and yellow colours of the latter being produced by an admixture of iron in different states of oxidation. The most magnificent crystals of emerald occur in veins of magnesian carbonate of lime, which traverse a hornblende rock in the mine of Muso, near Santa Fé de Bogota, in Peru. A hexagonal prism from this locality, upwards of two inches in length, and measuring across its three diameters $2\frac{1}{4}$, $2\frac{1}{8}$, and $1\frac{7}{8}$ inches, is now in the possession of the Duke of Devonshire: it weighs eight ounces and eighteen dwts. and, though imperfect for the lapidary's purposes, from the numerous flaws it contains, is unquestionably the finest crystallized emerald at present in Great Britain. Less distinct varieties, generally of muddy emerald-green colours, occur imbedded in mica slate in the Pinzgau valley, Saltzburg; also in mica-schiste at Mount Zabara in Upper Egypt, a locality whence the ancients are believed to have obtained their emeralds.

The Peruvian emerald, according to the analyses of Klaproth and Vauquelin, contains,

Silica	68·50	64·50
Alumina	15·75	16·00
Glucina	12·50	13·00
Oxide of iron	1·00	0·00
Oxide of chrome	0·30	3·25
Lime	0·25	1·60

Its specific gravity ranges between 2·6 and 2·8, and its hardness between 7·5 and 8·0 of the scale of Mohs; that is, it scratches quartz, and is very little inferior to topaz in hardness. It possesses a vitreous lustre, more or less shining, and a conchoidal, uneven fracture. By friction it becomes electric, and before the blowpipe with borax fuses into a transparent colourless glass. But it is as a gem inferior only to the diamond and the ruby that this mineral is so highly prized and esteemed. Its colour, which is perfectly distinct from that of any other gem, is the richest, and presents by daylight the most pleasing hue imaginable. An emerald, therefore, possessing considerable surface, and free from flaws and impurities, has always been very highly prized, and, according to Pliny (lib. xxxvii.), even in his time commanded immense sums. Haüy describes one in the tiara of the sovereign pontiff when in Paris in 1804, consisting of a cylinder about two inches long by two and a quarter broad, which is supposed to have been brought from Africa, as it bears the name of Julius II. who flourished anterior even to the conquest of Peru. The most magnificent cut emerald in this country is that in the possession of Mr Hope of London: it weighs six ounces, is perfect in colour and transparency, and cost L.500. It is believed to be from Coimbetoor.

Emeralds are cut and polished with facility. The usual form given them is that of a square table with the edges replaced, the lower surface being cut into facets parallel to their sides. When fine they are always set without a foil, and, in consequence of their brilliancy being somewhat impaired by candle light, are generally surrounded with small diamonds or pearls, which on such occasions add considerably to their lustre and effect. This gem has been imitated by the manufacturers of paste stones in France with very considerable success, the colouring matter which they use being the oxide of chrome.

EMERSION, in *Physics*, the rising of any solid above the surface of a fluid specifically heavier than itself, into which it had been violently immerged or thrust down.

It is one of the known laws of hydrostatics, that a lighter solid being forced down into a heavier fluid, immediately endeavours to emerge, and that with a force or momentum equal to the excess of weight of a quantity of the fluid above that of an equal bulk of the solid. Thus, if a solid be immerged in a fluid of double its specific gravity, it will emerge again till half its bulk or body be above the surface of the fluid.

EMERSION, in *Astronomy*, is when the sun, moon, or other planet, begins to re-appear after having been eclipsed, or hid by the interposition of the moon, earth, or other body.

The difference of longitude is sometimes found by observing the immersions and emersions of the first of Jupiter's satellites. The immersions are observed from the time of Jupiter's being in conjunction with the sun to his opposition, and the emersions from the opposition to the conjunction; two intervals which are usually six months each, and divide the year between them. But when Jupiter is in conjunction with the sun, and fifteen days before and afterwards, there is nothing to be observed, the planet, with his satellites, being then lost in the light of the sun.

EMERSION is also used when a star, before hid by the sun, as being too near him, begins to re-appear and to get out of his rays.

EMERSON, WILLIAM, an eminent mathematician, was born on the 14th May 1701, at Hurworth, a village about three miles south of Darlington; at least it is certain that he resided here from his childhood. His father Dudley Emerson taught a school, and was a tolerable proficient in mathematics; and without his books and instructions, perhaps his son's genius, though eminently fitted for mathematical disquisitions, would have never been unfolded. The latter was instructed in the learned languages by a young clergyman, then curate of Hurworth, who was boarded at his father's house. In the earlier part of his life he attempted to teach a few scholars; but, whether from his concise method of explaining his ideas, in which he was not happy, or from the warmth of his natural temper, he made no progress in his school; he therefore soon left it off, and, satisfied with a moderate competence left him by his parents, he devoted himself to a studious retirement. Towards the close of the year 1781, being sensible of his approaching dissolution, he disposed of the whole of his mathematical library to a bookseller at York; and on the 20th of May 1782 he died of a lingering and painful disorder, at his native village, in the eighty-first year of his age.

Mr Emerson in his person was rather short, but strong and well made, with an open countenance and ruddy complexion. He was exceedingly singular in his dress and manners, and his appearance, which was rather clownish, if not boorish, did not bespeak the man of science; but his eccentricities were more than atoned for by the uncompromising independence of his character, and by the possession of strong natural parts, of which he has left ample evidence in his writings. He always walked up to London when he had any thing to publish, and revised it sheet by sheet himself. It was a favourite maxim with him to trust no eyes but his own. He never advanced any mathematical proposition which he had not first tried in practice, constantly making all the different parts himself on a small scale, so that his house was filled with all kinds of mechanical instruments together or disjointed. Fishing was a diversion which he was remarkably fond of, and while engaged in it he would frequently stand up to his middle in water. He used to study incessantly for some time, and then seek relaxation by taking a ramble to any pot-ale-house where he could get any body to drink with and talk to. The Duke of Manchester was highly pleased with his company, and used often to come to him in the fields and accompany him home, but could never persuade him to get into a carriage. He was a married man, and his wife used to spin on an old-fashioned wheel, of which a very accurate drawing is given in his Mechanics. He was deeply skilled in the science of music, the theory of sounds, and the various scales both ancient and modern, but as a performer he had nothing to boast of.

The following is a list of Mr Emerson's works: 1. The Doctrine of Fluxions, 1748, 8vo; 2. The Projection of the Sphere, orthographic, sterographic, and gnomical, 1749, 8vo; The Elements of Trigonometry, 1749, 8vo; 4. The Principles of Mechanics, 1754, 8vo; 5. A Treatise of Navigation, 1755, 12mo; 6. A Treatise of Algebra, in two books, 1765, 8vo; 7. The Arithmetic of Infinites, and the Differential Method, illustrated by Examples, 1767, 8vo; 8. Mechanics, or the Doctrine of Motion, 1769, 8vo; 9. The Elements of Optics, in four books, 1768, 8vo; 10. A System of Astronomy, 1769, 8vo; 11. The Laws of Centripetal and Centrifugal Force, 1769, 8vo; 12. The Mathematical Principles of Geography, 1770, 8vo; 13. Tracts, 1770, 8vo; 14. Cyclomathesis, or an easy Introduction to the several branches of the Mathematics, 1770, in 10 vols. 8vo; 15. A short Comment on Sir Isaac Newton's Principia; to which is added, A Defence of Sir Isaac against the objections that have been made to several parts of his works, 1770, 8vo; 16. A Miscellaneous Treatise, containing several Mathematical Subjects, 1776, 8vo.

EMERY, a rich iron ore, found in large masses of no determinate shape or size, but extremely hard and very heavy. It is usually of a dusky-brownish red on the surface; but when broken it is of a fine bright iron grey, though not without some tinge of redness, and is spangled all over with shining specks, which are small flakes of a foliaceous talc, highly impregnated with iron. It is found in some of the Greek islands, in Tuscany, and in some parts of Germany.

EMIGRATION.

The natural propensity of mankind is to settlement and rest, and this principle is still further strengthened by the influence of local associations over the mind. Every one is strongly attached to the place of his birth, or to the place where he has passed his earlier years; and it may be generally remarked, that, in whatever spot man fixes his abode, there he takes root. Habits and sympathies are created, strong attachments are formed, and the longer he remains in any particular place, his aversion to change grows upon him. The power of early associations over the mind is exemplified by constant experience. How many of those adventurers who, at an early age, had quitted their home and their country in pursuit of fame or fortune, do we see daily returning to revive those local affections which, being deeply impressed on the heart while it was yet warm and susceptible, neither time nor distance has been able to efface. And to the powerful influence of the same tender recollections are we to ascribe that painful longing and deep despondency to which the Swiss and other nations are liable when they have been long absent from their country and their home. Such being the general disposition of mankind to rest where their lot is cast, such the various and powerful ties by which they are attached to particular spots, and so general their aversion to change, we may fairly conclude, when we see the inhabitants of any country eagerly engaging in projects of emigration, in opposition to their natural attachment to their native land, and in defiance of all the uncertainty and peril of a new settlement on a distant and unknown shore, that their conduct is not the result of choice, but of necessity; and that, in thus leaving their kindred and their country, they are flying from the pressure of some great and general misery.

General view of the subject.

The great and radical evil which afflicts society is the want of food, which necessarily arises from the tendency of mankind to increase faster than the means of subsistence can be provided. The importance of this great law of nature, under which the want of food is everywhere found to be the grand obstacle to the multiplication of the species, was first duly appreciated by Mr Malthus, who, in his profound and invaluable work *On Population*, has explained and enforced the principle with such elementary clearness and force, and with such various and striking illustrations, that it is now universally adopted as an indisputable maxim of political science.

According to the simple view of this interesting subject, contained in the work of Mr Malthus, it has been ascertained, from the history of the American and other newly settled colonies, that where there is abundance of food, the population has been doubled in some cases in twenty-five, in others in fifteen years; and it is obvious that if 10,000, or any other number of inhabitants, can be doubled within fifteen or twenty-five years, 20,000 or 100,000, or any greater number, may be doubled in the same period with equal facility. The increase of population takes place, therefore, according to a geometrical ratio; every successive addition affording the means of a still greater increase, until the earth being at length replenished with inhabitants, room and food are alike wanting for any farther addition to the human species.

It is not easy to determine the rate according to which the productions of the earth may be supposed to increase. This will in a great measure depend on accidental circumstances. Where there are extensive tracts of fertile and unoccupied land, food will be produced in great abundance; but after these are all cultivated, and the less fertile parts of the country begin to be settled by its increasing inhabitants, subsistence will be produced at a slower rate, and with greater toil. In this manner, we find, the population continues to advance according to an accelerated process, the increase of one period only affording the means of a still greater increase during the next, and this without any limit; whilst the subsistence for this rapidly increasing population, instead of being produced with the same facility, instead of increasing in proportion to the growing wants of the community, is necessarily produced at a slower rate, and with greater toil, at the period when it is most wanted. Whilst the principle of population is yet in full vigour, and is every day acquiring new powers of increase, the produce of the earth is daily procured with greater difficulty. The same causes, therefore, which occasion a continual multiplication of inhabitants, prevent any progressive increase in the supply of provisions. By a long process of skilful cultivation, the earth may at last reach the utmost limits of its productive powers. This state of things, it is supposed, has already taken place in China. No efforts of human industry, however judiciously directed, could ever probably double the produce of this highly cultivated country. But the population could still be doubled in fifteen or twenty years with the same facility as before. All countries which have been long settled and cultivated, are in some measure in a similar condition. No efforts of human skill could possibly draw from Great Britain double its present produce within the period during which its population could be doubled; and in all such countries, therefore, the further increase of inhabitants is checked by the want of food. It is manifest, indeed, that the number of people in any country, or in the world at large, must be limited by the quantity of subsistence provided for their support.

But though it is certain that the population of every country must be kept within the limits of its food, this object may be accomplished by the operation of two different causes. 1*st*, General habits of refinement, or prudential motives, such as the fear of bringing children into existence without the means of supporting them, may so far operate on the minds of the labouring classes as to discourage marriage; in which case no superfluous inhabitants will be produced, and the supply of food, though it will admit of no increase, will still be sufficient for the maintenance of the population already in existence. Where the want of food operates in this manner to check the progress of population, Mr Malthus distinguishes it by the appellation of the *preventive* check. 2*dly*, So strong, however, is the impulse by which man is prompted to multiply his species, that this preventive check seldom operates with sufficient force to restrain the undue increase of population. In all countries mankind have a perpetual tendency to increase faster than food can be provided; and even when the preventive check operates with most effect, the population frequently presses on the very verge of its subsistence, and is thus exposed, by an accidental failure in the ordinary supply of food, to all the miseries of want. As the number of inhabitants is necessarily restricted by the supply of subsistence, it is certain that, if the population increases beyond this limit, it will speedily be brought down to the level of its food by the operation of famine and disease, which Mr Malthus terms the *positive*, in opposition to the *preventive* checks to population.

From this view, then, of the natural and immutable condition of human society, the want of subsistence seems to be a necessary and an inherent evil, under every form of it; to avoid which, mankind, as they begin to increase, are forced to separate in quest of new settlements, in which, the inhabitants being fewer, food is more easily procured. The want of subsistence is therefore the universal and constant cause of emigration, which forces mankind to disperse themselves, and to explore the world for a more desirable abode. It is no love of change or of adventure which prompts them to wander into unfrequented parts. It is the urgent pressure arising from an overcrowded population which impels them from their homes, which breaks the ties of kindred, and forces them to encounter all the hardships and dangers of new and untried scenes. Where a community is happy and prosperous, mankind will follow their natural propensity to settlement and rest; and it is only when this principle is disturbed by an opposite and equally powerful principle, namely, the fear or the actual experience of want, that emigration will be resorted to, as the least of two evils, not from choice, but from necessity. It is under the influence of this great law of nature, namely, the tendency of mankind to increase faster than food can be provided for them, that the earth has been overspread with inhabitants. From the original seats of population and improvement, the human race would naturally overflow into other parts. The regions which were most desirable from their happier soil and climate would be first occupied; these being replenished with people, the overflowing stream would naturally reach the less habitable parts, until at length the frozen regions of the north and the burning climes of the south would be fully peopled, in proportion to the scanty subsistence to be drawn from them by an unskilful and barbarous race.

The earth being in this manner filled with people, and no more vacant space remaining for new emigrations, the great check to population, from the want of subsistence, must now be felt in all its force; and it is evident that no further increase of inhabitants can take place, unless new modes of subsistence be contrived, by which a greater supply of food may be derived from the same extent of territory. The most primitive and barbarous mode of life ever found to prevail among mankind, is when they depend for subsistence on hunting and fishing, or on a casual supply of such produce as the earth spontaneously yields. From the humble and degraded condition of hunters, they gradually emerge into that of shepherds; and while their flocks and herds afford them a more certain provision, the care of these necessarily calls forth a greater degree of foresight than belongs to the hunting tribes; and the community being also in possession of a stock for their immediate subsistence, are in every respect in a superior condition to mere savages. It is in the agricultural state, in which a community, adopting all the most ingenious and successful modes of cultivation, and improving at the same time in all the arts of commerce and industry, gradually accumulates capital and acquires habits of luxury and refinement, that the earth supports the greatest number of inhabitants; and to this state therefore mankind, impelled to improvement by the stimulus of necessity, continually tend. But as the course of improvement is retarded by a variety of causes, it has always happened that, in the general population of the world, three classes have been comprised, who, though variously modified, may be distinguished into those of hunters, shepherds, and agriculturists. When the earth is wholly occupied with these different communities, in each of which the population, according to the great law by which it increases, will soon reach the utmost limit of its food, it is manifest that the great standing cause of emigration will be in constant operation; and in this case there is little doubt that numbers will incur the risks of a removal for the sake of improving their condition.

The inhabitants of a country may emigrate individually, in which case they will be incorporated with the new community into which they enter, and their settlement will be made without violence; or a whole nation may emigrate, with a view of making their way to new settlements by the sword, and of driving out by force the inhabitants of the territory into which their irruption is made. Among civilized nations it is scarcely possible that this mode of emigration can take place. No government would countenance its subjects in any predatory irruption on the territory of another state; neither would the wealth acquired by civilized communities, nor the habits of order, industry, and peace, which wealth necessarily superinduces, at all consist with any such hostile enterprises against the repose of other nations. In an advanced state of society, therefore, the license of emigration is in some degree restrained; mankind emigrate individually, but not in large bodies, and in this manner they are quietly absorbed in the new communities into which they enter, and to the laws and manners of which they necessarily conform. But though the civilized communities of the world never violently emigrate into each other's territories, they frequently invade the domain of the savage, by obtruding new settlers on his uncultivated territories. These emigrating in considerable bodies, and being provided with every necessary implement either of cultivation or of war, take possession of the soil, which they cultivate for their support, and, gradually increasing in proportion as their improved modes of cultivation draw an increased produce from the soil, all the efforts of the original proprietors to dislodge them are found unavailing. From such small beginnings it is that, in modern times, all the flourishing communities of the new world have had their origin.

Amongst the barbarous nations of hunters and shepherds, emigration necessarily assumes the character of violence. The earth being already occupied with inhabitants, it is manifest that no large body of emigrants can effect a settlement in any territory without displacing an equal proportion of the original inhabitants. These, however, will not yield without a struggle; wars naturally commence, which are carried on with an inveteracy suited to the important object at stake; and while the conqueror occupies the vacant ground, the world is thinned of its superfluous inhabitants in these contests for room and food.

The want of subsistence, which thus excites in mankind a restlessness and an impatience of their condition, and finally impels them to emigration, appears, from the experience of all history, to be a most fruitful cause of war; and, in these struggles, the mere savage has little chance against the more formidable violence either of the pastoral tribes or of civilized communities. By the first he is driven from his ground whenever it can be occupied with advantage for the purposes of pasture; while the civilized inhabitants of the globe occupy his territories with new settlers, who, spreading cultivation over the desert, and establishing towns with all their refinements of arts and manufactures where there was formerly a wilderness, destroy the hunting grounds of the savage, and expel him, with the wild beasts, his natural prey, from these seats of industry. Thus driven farther into the woods, he is reduced to fight for his subsistence with other tribes in the same condition as himself, and with whom he has more chance of waging an equal war. Room and subsistence being indispensable to the further multiplication of the species, every combined movement among mankind in quest of these objects is the signal of discord; the savage tribes, confined to the more remote and unfrequented parts of the earth, mutually exterminate each other by their constant and ferocious hostility; and the pastoral nations carry on equally destructive contests with each other, or with more civilized communities. Barbarism and civilization are in this manner the natural enemies of each other; and a most inveterate war is the inevitable consequence of this hostility. On the issue of the contest the very existence of both parties is staked. To the vanquished nothing remains but to perish by famine or the destroying sword. If the barbarous invaders prevail, all traces of civilization are swept away—the form of society is changed—its institutions destroyed, and the nation itself reduced under the most degrading bondage. If, on the other hand, the barbarians are repelled, they have no refuge from destruction. There is no alternative between victory and death; and thus both parties mutually fight with the fury of desperation. But, where the resources of a civilized state are vigorously called forth for the common safety, those formidable inroads will be generally repelled, and the country saved from the ignominy of a barbarian yoke.

Emigrations by which the Roman empire was overthrown.

To this principle, namely, the disproportion between the increase of subsistence and of population, we may trace that spirit of emigration and of conquest which prevailed universally amongst all the pastoral nations of the ancient world. The character and manners of those rude tribes have been powerfully delineated by the eloquent historian of the Roman empire; and Mr Malthus has added a fine historical sketch of the rise and progress of those emigrations which, after a long train of political convulsions, terminated at length in the subversion of the Roman power. It appears that all that vast portion of the earth, from the Danube and the shores of the Baltic to the confines of China, was formerly occupied by a population of shepherds. These, though distinguished into separate nations, possessing a strong principle of unity in the common tie of their congenial manners, easily coalesced under an enterprising leader for any scheme of emigration or conquest. Deriving their subsistence from pasture and the chase, their ordinary life was one of constant migration, in which they were inured to fatigue, and instructed in the use of all warlike weapons; they were skilful horsemen, expert in archery and in throwing the lance, and extremely active in all their movements. In this wide ocean of barbarism, the stream of emigration was either impelled eastward, as accidental circumstances directed, against the flourishing empires of Asia, or westward against the Roman empire, within whose precincts the whole civilization of the western world was comprised; and alternately, as it reached either of these empires, their whole collected strength was found necessary to withstand the shock. Of the great empires of Asia, some were subverted by the formidable inroads of those wandering tribes; and in Europe the doubtful balance of the world's destiny frequently trembled between barbarism and civilization. At an early period Rome was assailed by the inroads of the barbarians, and an irruption of the Gauls had well nigh crushed her rising power. In after times the Cimbri, emigrating in quest of new settlements, were, after they had destroyed five consular armies, arrested in their victorious career by Marius, when the whole nation almost was exterminated. The subsequent contests of Julius Cæsar, of Drusus, Tiberius, and Germanicus, with the Gauls and Germans, still attested the superiority of the Roman arms, and impressed upon the barbarians a salutary terror of the Roman name. Repelled from the Roman frontier, their superfluous resources would naturally be consumed in intestine wars with each other for room and subsistence, until the power of population renewing the strength of those warlike communities, prepared them for fresh conflicts with the civilized world. Accordingly we find them, in the decline of the empire, renewing their irruptions on the Roman territory. During the successive administration of a series of feeble princes, the empire was assailed by new swarms, and the degenerate Romans had recourse to the dangerous policy of bribing the enemy whom they could no longer conquer. This fatal disclosure of wealth and weakness soon excited the cupidity of new enemies, who broke through the ill-guarded frontier, and spread terror to the gates of Rome. The country became one universal scene of rapine and oppression, and it was only by the vigour and activity of Aurelian, Probus, and Diocletian, that the tottering empire was saved from its final overthrow. During this interval the barbarians wasted their population in bloody hostilities with each other, until nature, more powerful to renovate than war to destroy, recruiting their numbers, enabled them to set out on new emigrations with undiminished strength. During the reign of Constantine, the whole power of the empire was again called forth to repel a new invasion of those destroying hordes. They were vanquished on every side, and driven into the mountains, where it is calculated that about 100,000 of them perished from cold and famine. Other invaders now arose, who were routed and dispersed with great slaughter by the warlike Julian, and pursued into the gloomy recesses of the German forests; but those signal successes obtained for the declining empire no relief from incessant attacks, and the reign of Valentinian was one continued contest with the invading hosts. "The fate of Rome," Mr Malthus observes, "was at length determined by an irresistible emigration of the Huns from the east and north, which precipitated on the empire the whole body of the Goths;" and the nations of Germany, goaded on by this powerful impulse, were driven *en masse* on the Roman provinces. "An emigration," Mr Malthus continues, "of 400,000 persons issued from the same coast of the Baltic which had poured forth the myriads of Cimbri and Teutones during the vigour of the republic. When this host was destroyed by war and famine, other adventurers succeeded. The Suevi, the Vandals, the Alani, the Burgundians, passed the Rhine never more to retreat. The conquerors who first settled were expelled or exterminated by new invaders. Clouds of barbarians seemed to collect from all parts of the northern hemisphere. Gathering fresh darkness and terror as they rolled on, the congregated bodies at length obscured the sun of Italy, and sunk the western world in night."

So long as such an extensive space of Europe and Asia was occupied by these pastoral tribes, the repose of the civilized world was constantly assailed by their barbarous invasions; and, in the course of their various expeditions, the finest countries of Europe were taken possession of and plundered. The same principle of increase which was the original cause of all these movements, still continued to operate with undiminished force; but while the central countries of Europe remained in possession of their recent conquerors, there was little chance of easily wresting from them what they had so hardly won; and the spirit of emigration being therefore checked and confined for a time within narrower limits by land, the barbarous nations of the north found vent for their overflowing numbers by sea. During the distractions which ensued in Europe subsequently to the reign of Charlemagne, their maritime enterprises were prosecuted with great vigour, and they spread their devastations over Lower Saxony, Friesland, Holland, Flanders, and other countries. They ravaged the coasts of France, pillaging and burning her finest towns, and at length obtained possession of some of her finest provinces. The British isles were for two hundred years exposed to their ravages; and, during the eighth, ninth, and tenth centuries, their plundering expeditions were directed against all the most powerful nations in Europe, until at length the improving powers of these countries, developed by civilization, and directed by policy, were found sufficient to repel all such irregular inroads. It was in this manner that the growing strength of the European states laid the foundation for that important change of manners among the northern nations, under the influence of which habits of emigration and plunder have been superseded by the peaceful pursuits of agriculture. From this period the repose of the civilized world has never been seriously endangered by the migrations of any barbarous nation; and it is not likely that such contests will ever be renewed. The pastoral tribes were formidable from the vast space over which they were allowed to range. They are now reduced within much narrower limits. Most of them have been reclaimed from their rude habits and trained to industry. What has been thus lost to savage life has been gained by civilization. The resources of the one have been increased as those of the other have diminished. It does not appear, therefore, from the present aspect of the world, that civilized man has any farther injustice to dread from his savage brethren. These views are eloquently enforced by Gibbon, in the philosophical and striking view of the leading causes which conduced to the fall of the western empire, with which he closes his history. "Such formidable emigrations," he observes, "can no longer issue from the north; and the long repose which has been imputed to the decrease of population, is the happy consequence of the progress of arts and agriculture. Instead of some rude villages, thinly scattered among its woods and morasses, Germany now produces a list of two thousand three hundred walled towns; the Christian kingdoms of Denmark, Sweden, and Poland, have been successively established; and the Hanse merchants, with the Teutonic knights, have extended their colonies along the coast of the Baltic as far as the Gulf of Finland. From the Gulf of Finland to the Eastern Ocean Russia now assumes the form of a powerful and civilized empire. The plough, the loom, and the forge, are introduced on the banks of the Volga, the Oby, and the Lena; and the fiercest of the Tartar hordes have been taught to tremble and obey. The reign of independent barbarism is now contracted to a narrow span; and the remnant of Calmucks or Uzbecks, whose forces may be almost numbered, cannot seriously excite the apprehensions of the great republic of Europe."

Character of the more modern emigrations.

In modern times, since the progress of improvement has restrained the license of those rude tribes, the spirit of emigration and conquest has chiefly appeared among the civilized inhabitants of the world, by whose encroachments the barbarous nations have been oppressed. The discovery of the immense continent of America, which was chiefly overspread with savage tribes, or with nations in the infancy of improvement, presented a vast outlet to the overflowing population of civilized Europe; and the reputed wealth of those newly discovered countries, which were found to contain abundance of the precious metals, soon attracted crowds of adventurers from every quarter. The first expeditions of the Spaniards to the New World were for the undisguised purposes of rapine and conquest. They were purely military, not so much with a view to settlement, as to plunder; and it was only after the first race of adventurers had perished, that the emigrants began to establish themselves permanently in the country. With this view they resorted to such measures of violence and cruelty, that in most cases they either extirpated the original inhabitants, or brought them under the most galling bondage; and in those parts of the country where they fled into the deserts beyond the reach of their oppressors, and where they subsist in savage independence, the cruel injuries which they originally suffered is still attested in their inveterate hostility to the Spanish settlers. The settlements of the European states in North America were not planned upon exactly the same principles of open violence. The savage tribes by which this portion of the continent was inhabited presented no such temptations to the avarice of civilized nations, and the first emigrants who were sent out had nothing else in view but to cultivate the country for their subsistence. Agriculture, and not conquest, was their original object. They offered no violence to the native tribes. All they required was a space of unoccupied territory on which to settle, which was generally procured without any difficulty. But as the colony grew and flourished, and began to require an extension of territory, the rude inhabitants of the country quickly perceived that they would soon be dispossessed of their hunting-grounds by the gradual increase of the new settlers. They had committed the capital error of allowing the colonists to take root in the country, and they now endeavoured to correct this error when it was too late. They accordingly entered into combinations for the purpose of exterminating the invaders of their country; and those infant establishments were alternately assailed by secret treachery or open violence. An equally inveterate warfare was in this manner begun with those who settled for the purposes of agriculture, as with those who had commenced their career with open violence; and the object of contest was the possession of the country. From the rapid multiplication of the new settlers, it was obvious that the land would be speedily overspread with their increasing numbers; and the whole being converted to the purposes of agriculture, there would be no room for the hunting tribes. This was the plain and obvious principle of the war which was now commenced. But the issue of a contest between the civilized inhabitants of the globe, assisted by the modern improvement of fire-arms, and the mere hunter of the desert, could not be for a moment doubtful. The arts and policy of Europe accordingly proved too powerful for the Indian savage. He has been gradually pushed back, by the progress of the European colonies, into his native deserts; and though he has occasionally disturbed their progress by his predatory inroads, yet the inveterate warfare in most cases subsisting between the aborigines and the new settlers, by saving all perplexing or fruitless negociations respecting the cession of territory, and by reducing the matter to the plain issue of force, has, upon the whole, favoured the progress of the civilized encroacher on the territory of the savage. The war of extermination which was commenced between the two classes, was sure to end in the destruction of the native inhabitants. A quicker process, indeed, could scarcely have been devised for clearing the country of its barbarous incumbrances; and, however cruel and unjust this may appear, such are unquestionably the harsh means by which the improvement of the North American continent has been brought about. The poor savage has been driven from his territory and his home, to make way for the industrious tiller of the ground. The boundaries of the wilderness have been gradually narrowed by the progress of cultivation; the country has been cleared of its forests and of its inhabitants by the same merciless process of destruction; and upon the ruins of this state of society the system of social improvement has been reared. To the doubtful frontier of the American territory, where civilized gives place to savage life, it is well known that crowds of adventurous emigrants resort, dispensing with the advantages and exempted from all the restraints of social life. Here they act in the double capacity of cultivators and huntsmen, partly civilized and partly savage, until, by the advance of new emigrants, they are gradually surrounded with improvement on every side, and are at length brought within the pale of order and law. Tired of this control, and anxious to resume their free and licentious habits, they dispose of their lands to emigrants of a more settled character, and again take their station on the verge of the desert, there to bear the brunt of savage hostility, to hunt and to cultivate, and by their resolute and ferocious habits to repress the inroads of the exasperated Indians, and to act the part of successful pioneers, in clearing the way for the great mass of the American population. It is in this manner that the country gradually assumes the aspect of civilization, that the fields are cultivated, and that the dwellings of men are seen to take place of the haunts of wild beasts. It is certain, indeed, that the policy of the American government, in regard to the native tribes, has uniformly been humane and enlightened; their original right of occupancy has always been respected, and the cession of their territory has generally been procured in lieu of some satisfactory equivalent offered and received, or a certain portion of it has been reserved out of the lands granted to new settlers for their subsistence. But the licentiousness and cruelties under which the Indians have been oppressed were committed by individuals beyond the precincts of law or government—they were, besides, glossed over under the specious disguise of legitimate hostility; and there was no one to plead the cause of the oppressed Indians. In these circumstances the power of government could be exerted with little effect in favour of the native tribes; and accordingly it is matter of history, that many of the finest parts of the American territory were with difficulty wrested from their original possessors, after a most severe and sanguinary struggle.

Notwithstanding the tendency of mankind to increase faster than food can be provided for them, and the rapid progress of cultivation among civilized nations, a great proportion of the earth is still occupied by savages, who subsist by hunting, and who allow the land to lie waste; or by pastoral tribes, who require a much larger space for their support than agricultural nations; and hence the tide of emigration naturally flows from the cultivated parts of the earth to desert or less cultivated tracts. The continent of America contains at present the largest space of unoccupied land that is to be found in any part of the earth; and it presents, accordingly, a vast outlet to the surplus population of the old and settled communities of Europe. So great also is the extent of this continent, ranging as it does over more than a hundred and twenty degrees of latitude, that the emigrant may choose the climate and the country most congenial to his previous habits. In South America, Chili, with a mild climate and a fertile soil, presents vast tracts of desert territory, well suited to the inhabitants of southern Europe; and on the boundless plains of Buenos Ayres a vast additional population might subsist. The mountainous tracts of Brazil, and the luxuriant valleys that intervene, are still mostly in a state of nature; and to the overflowing population of Spain and Portugal they present a sure asylum for ages to come. The tropical countries in America that approach nearer to the equinoctial line are not so well adapted to European emigrants, their health generally suffering under the enervating influence of the climate; and it is not likely therefore that the arts, the intelligence, and industry of the old world will ever flourish to a great extent in these uncongenial regions. But in North America, in the territory of the United States, or in the British colonies of the Canadas, Nova Scotia, New Brunswick, and their dependencies, every thing concurs to favour the views of the European emigrant. The territory of the United States, stretching from the Gulf of Mexico to the river St Lawrence, comprises great variety of climate, and tracts of singular fertility, on which may be produced all that is necessary for the comfort and enjoyment of man. The numerous streams which everywhere intersect the country, facilitate in a remarkable degree its internal intercourse, while it is further recommended to new settlers by the advantage of its free government, which dispenses equal protection to all. To the north the British settlements present a great outlet to the overflowing population of Europe, and especially of Great Britain. The Canadas, and particularly the upper country, abound in the most fertile tracts, skirted by the great northern lakes which flow into the ocean through the St Lawrence, or intersected by their numerous tributary streams. The winter is tedious and severe, with a dry atmosphere and a clear sky; and the climate, except in particular situations, is not unfavourable to European constitutions. In Nova Scotia and New Brunswick, the winters are still more severe than in the Canadas; and fogs and mists also prevail. But the country is healthy, and the soil yields abundantly European grain, vegetables, and fruit. In all those countries cultivation has made comparatively little progress, and there are in the interior vast tracts of unoccupied territory, which would yield subsistence to additional millions.

America the great outlet to emigration.

In its present condition, therefore, America presents a grand outlet to the surplus population of Europe. It is the natural asylum of all those who are flying in quest of subsistence from the over-crowded communities of the old world. The inhabitants of America have before them an untouched and fertile country, about 2000 miles in extent (counting from their most remote settlements to the Pacific Ocean), in which for centuries to come their population will have full scope to expand. Here there is an ample supply of fertile and unoccupied land, which yields abundance of food, while its cultivation gives rise to a constant demand for new labourers. Wages are consequently high, the labourer lives in comfort; and if he is industrious, he becomes in his turn a purchaser of land, from the savings which he accumulates. If from the rapid increase of population, the demand for labour should be satisfied, and wages should fall, this is the signal for new emigrations, and for the occupation of an additional portion of the uncultivated territory; and thus the abundance of land and the constant demand for labour in the western districts, maintains it at a high price in every part of the United States, as well as throughout the British colonies of North America.

Asia contains vast tracts of territory, either wholly uncultivated or occupied by pastoral tribes, which might be colonized with great advantage by a more civilized population. But those regions, from various causes, from their distance inland, from the disorderly state of society which prevails in most parts of Asia, and from dissimilarity of language and manners, are mostly inaccessible to European colonists. In the Asiatic dominions of Russia, population has been making in some parts a rapid progress; and settlers are gradually, though slowly, spreading over those wastes which were formerly occupied by Tartar hordes. In the vast steppes and meadows watered by the

Irkutsk, the Obi, and the Lena, range many vagrant tribes, that live by pasture or hunting; and here millions of additional inhabitants might easily subsist. But it is only from Russia that new settlers can be received; and centuries may elapse before the slowly increasing population of that empire overflow into such remote regions.

Great Britain has acquired on the continent of Asia the extensive empire of Hindustan and the large island of New Holland; and to both of these countries numerous emigrants resort. But Hindustan is exclusively the resort of the richer classes; the civil and military service of the East India Company affords employment to young men of talent and education; and now that India has been freely laid open, by the late act for regulating the company's affairs, to the capital and intelligence of Europe, numerous settlers from among the enterprising youth of Britain will no doubt be attracted to that land of promise. But to settlers of another description, to mechanics, labourers, or farmers, India holds out no encouragement whatever. On the other hand, it is entirely to this class of emigrants that the British colonies of New South Wales and Van Diemen's Land are so well suited. This great island of New Holland is begirt around four-fifths of its coasts by a circle of barren waste. But within this girdle the country improves, and presents abundance of fertile land, which might be occupied with great advantage by new settlers. Van Diemen's Land is still better adapted to colonists from Britain. It is situated between 40. 42. and 43. 43. south latitude, has a European climate, and a fertile soil. In this newly settled country, as in the United States and British America, provisions are abundant, labour is in great demand, and wages are high.

In Europe the state of things is altogether different; there the population has long pressed against the limits of subsistence; wages in many parts are consequently low, and the condition of the people wretched in the extreme. In Great Britain the misery of poverty has been of late years so deeply felt, that many have recommended that schemes of colonization should be undertaken at the public expense. A committee of inquiry was appointed by the House of Commons, who, after a laborious examination of evidence, published a report on the subject in 1827. This report contains an instructive detail of the present condition of the labouring classes in England, Scotland, and Ireland; from which it appears that in all these countries, especially the latter, population has greatly increased; there are more people than can be employed; the rate of wages is low; and the condition of the labourer is depressed. From the concurring evidence of all the witnesses who have appeared before the different committees of the House of Commons, the condition of the Irish labourers appears to be wretched in the extreme. Population is in Ireland pushed to the very verge of subsistence; the labourer, who has scarcely a bare support from the cheapest food, exists in hopeless degradation and misery; and the least failure of the supply involves thousands in actual starvation. Ireland is so oppressed by superfluous inhabitants, that they overflow into the adjacent countries; and neither England nor Scotland can shut out this contagion of misery. They are inundated by Irish labourers, who bring down the wages of labour, and thus the effect of Irish poverty is to deteriorate the condition of the working classes, not merely in their own, but in other countries.

Such being the condition of the labourer in Ireland, and in some degree also in Great Britain, it is manifest that if he can transport his labour from these overstocked markets to the understocked markets of the United States, or the British colonies in North America or New Holland, he will dispose of it to better advantage. He will unquestionably improve his own condition, while it is obvious, if there is too little either of subsistence or of employment in any country, the emigration of those who require to be employed and to be fed will leave a greater supply for those who remain behind; and hence it is extraordinary that an outcry should have been raised against the emigrants, by those who were enabled by their happier destiny to remain at home. To such length has this spirit been carried, that laws have been passed, obstructing emigration, as if it were an evil; and, with a view of still further discouraging all such schemes, the most exaggerated accounts have been studiously circulated of the distresses and difficulties in which the poor emigrant involves himself by rashly removing to a foreign land. In the Highlands of Scotland, emigration has always been viewed by the landed proprietors with the most extreme jealousy and aversion, although it plainly has its origin in the measures adopted by themselves for the improvement of their own estates. The first step to an improved mode of cultivation is to clear the land of all its useless inhabitants; and the discarded tenants are compelled to seek in a distant land that subsistence which they can no longer find at home. Emigration is the sad alternative which they embrace from necessity; they quit the cherished spot on which their family has been settled for ages, because they can no longer remain, and to refuse them this resource appears both cruel and unreasonable. Under the influence of those prejudices, a law was passed in 1803, for the ostensible purpose of securing to the emigrant good treatment during his voyage, but really with a view, it should seem, of obstructing it altogether. By this law, the most extravagant allowances are prescribed to him, both as to room and food, and these he is not at liberty to dispense with. Its effect is consequently to enhance the expense of the voyage, and to obstruct emigration, or, when this consequence does not follow, to waste the stock of the emigrant, by involving him in useless expenses, and to land him on a foreign shore with diminished resources. It tends, in this manner, like all the other laws which, in the management of private concerns, officiously substitute loose and inapplicable rules for the prompt sagacity of individual prudence, to injure those whom it is intended to serve. By other laws, emigration, to certain classes, is actually prohibited under severe penalties. An artificer who attempts to emigrate "with the intention of devoting his knowledge for the benefit of foreign countries," is liable to punishment, as well as any agent by whom he is encouraged to such an attempt; and, upon this very absurd law, two convictions actually took place at the Old Bailey in 1809; the one of a master, who had offered an artificer advantageous terms to emigrate to the United States, and the other of the artificer, who, having no work at home, had accepted of these terms. It deserves to be remarked, that the judge who tried the case, forsaking his own proper province of merely administering the law, commended highly its policy, and dwelt at great length on the mischievous crime with which the prisoners stood charged, as deservedly and severely punishable by law. It is justly observed by Dr Smith, that the industry of an artificer is his only inheritance, and that to prevent him from disposing of it to the best advantage is an unwarrantable act of power. The object of such regulations is to depress the art and industry of other nations, in order to monopolize for our own industry the market of the world. But this project, which originates in mercantile rivalry of the most pitiful description, is as unjust as it is impolitic. We may indeed prevent, by particular laws, the exportation and importation of certain sorts of produce. But no laws can bind up the inventive powers of man, nor can any partial enactments of particular countries retard the improvement of the world. If the general increase of wealth requires a supply of the finer manufactures, and the proper reward is offered, the art and industry necessary to produce them will be called forth, in spite of the regulations which any one state may pass to the contrary. The law, besides, admits of the following simple evasion: the artificer who intends to emigrate takes his passage as a labourer, and, in this character, he is suffered to depart without further question.

It is clear, that in all cases where there is a greater number of labourers than can be employed, where wages are consequently low, and general distress prevails, emigration is precisely the most effectual remedy for the evil; and that, in proportion as superfluous labourers are withdrawn from the over-crowded communities of Europe, those who are left behind will enter into more full employment and better pay, and will live comfortably in place of starving as before. Whatever may become of the poor emigrants themselves, the country from which they emigrate must be benefited by the quantity of labour thus withdrawn from the market. In place of seeking to arrest the progress of emigration, it would be wiser to encourage it, and rather to give facilities to those who wish to convey their labour from Europe, where the market is overstocked, to those countries where there is a greater demand for it. In later times, accordingly, sounder notions have begun to prevail on the subject of emigration; and it has even been proposed to encourage it on a great scale, by advances of money from the public treasury, or by allowing the parishes to pledge the poor rates in order to furnish the necessary funds. In 1819 the sum of L.50,000 was granted by parliament to aid in settling a small body of emigrants at the Cape of Good Hope. But the climate is unfavourable to European habits, while various other discouraging circumstances obstructed the prosperity of the settlers; so that this experiment of colonization was far from being successful. In 1823 and in 1825, two bodies of emigrants were settled in Canada at the public expense. They received lands and were located on them; and, according to the accounts of those who have since visited them, they have attained to great prosperity and comfort. The last colony consisted of 2024 persons; the expense of settling them was L.43,145, rather more than L.20 for each person; and the superintendent of the undertaking valued the produce of their first year's labour at L.11,272. The emigration in 1823 consisted of 568 Irish emigrants, and cost about L.22 for each emigrant; and it is certain that even this expense, under the careful management of individuals, might be reduced, and would probably not exceed L.13. It was stated by several of the witnesses before the select committee of the House of Commons, that, at an expense of L.60, a family of five persons might be established in such a state of comfort as to insure their happiness. Colonel Talbot, who settled between thirty and forty years ago in Canada, while it was yet a wilderness, and is now surrounded by 20,000 inhabitants, gives the same evidence; and he is farther of opinion that the settlers, if they were industrious, might repay the advances made to them, nay even the expense of their voyage to New South Wales.

The good effects of emigration, not only to the emigrant, but to those who are left behind, being in this manner apparent, it has been proposed that government should aid with the necessary funds, and that the experiment of emigration should be tried on a great scale. The emigration of those who are able to pay their own expenses, though it has been carried to a great extent, is said, and with truth only, to comprise the industrious well-doing class of labourers, who have realized some property, and who contribute to the prosperity of the community in which they live, and are therefore no burden; while it is the poor and starving labourer, who subsists at the expense of others, that it would be of the greatest advantage to send abroad; and it is on this account that many advocate the policy of a public advance of money for this purpose. The facts brought forward certainly afford all the encouragement that can be desired for some experiment of the nature proposed; which, if gone about with caution and vigilance, would establish the poor emigrants in ease and comfort, while it would tend generally to improve the condition of the labouring classes both in Great Britain and Ireland. For such objects it would no doubt be worth while to incur the hazard even of pecuniary loss. But though several successful experiments of emigration have been tried on a small scale, it is somewhat doubtful if they would succeed to a greater extent. A body of two thousand emigrants might be easily settled in the unoccupied lands of the Canadas, and other British colonies. They would be at once incorporated with the increasing population of these rising communities. But it might not be possible to make the same ready provision for 100,000 or 200,000 emigrants; and in this case we incur the danger of squandering the public money in a rash undertaking, and involving in misery those whom it was our intention to serve. Hitherto no great scheme of emigration has been set on foot at the public expense. Encouragements have, however, been offered of advances of money to individuals, to unmarried females, and also to families, desirous of emigrating to New South Wales and Van Diemen's Land. According to a return laid before the House of Commons, it appears that, up to the present time (June 1833), the emigrants to Australia who accepted of these terms consisted of 1200 unmarried females, and that they had received L.16,926; and of 819 families, consisting of 3109 persons, to whom was paid L.16,237. Several parishes have, however, contributed to send abroad labourers out of employment, who are supported from the poor-rates, and at a comparatively moderate expense have relieved themselves of the permanent burden of their maintenance; and such local schemes of emigration, conducted at the expense and under the superintendence of individuals, managed with economy and care, would probably be more successful than any great adventure of this nature, undertaken at the public charge. But the great majority of emigrants have hitherto gone abroad at their own expense.

The following is an account of the number of emigrants who have left this country from the year 1825 to the 31st of December 1832, as laid before the House of Commons.

	1825.	1826.	1827.	1828.	1829.	1830.	1831.	1832.
To the British Colonies............	8,741	12,818	12,648	12,084	13,307	30,574	58,067	66,339
Cape of Good Hope................	114	116	114	135	197	204	114	196
Australian Colonies..................	485	903	715	1,056	2,016	1,242	1,561	3,733
United States........................	5,551	7,063	14,526	12,817	15,078	24,887	23,418	32,872
Total...........	14,891	20,900	28,003	26,092	30,598	56,907	83,160	103,140

It has been already stated that the great cause of emigration is the want of subsistence, and that where a community is prosperous and happy, mankind will follow their natural propensity to settlement and rest. But this general cause is frequently aided by other causes, originating in those changes of manners to which the progress of society is constantly giving rise. In consequence of that great revolution which took place in modern manners when the feudal system was superseded in Europe by the progress of commerce and industry, the numerous retainers of the great landed proprietors were thrown loose upon society, and reduced to quit their former abodes in quest of a new settlement. Prior to the improvement of industry, there was no way in which the proprietors of the soil could consume their surplus produce, but in maintaining a retinue of idle dependents, who repaid, by their fidelity in war, the bounty on which they subsisted during peace. No equivalent existed for which they would exchange their revenues, which were accordingly wasted in the most profuse hospitality; and in these times a train of idle retainers was the never-failing appendage of wealth and greatness. But when commerce and industry began to supply the landed proprietors with a new equivalent in which their surplus produce could be expended, their idle retainers were gradually dismissed, and the surplus produce of the soil, by which they were supported, was now laid out by the landlord in expensive luxuries and refinements. In the more improved parts of the country, all those changes have already taken place. The land is invariably let for the highest rent that can be procured, and the superfluous population from which it has been freed is absorbed in the general mass of society. But in the Highlands of Scotland these changes are not yet fully accomplished. Traces are still to be discerned of that ancient state of manners which was formerly prevalent all over the country, but which is now fast disappearing before the progress of improved cultivation. Until about the year 1745, the landed estates in the Highlands of Scotland were occupied by tenants, who paid for the possession of the land rather in military services than in money; and though after this period these services were of little use to the proprietors, yet from habit, and the influence of old attachments, the tenantry were still continued on their lands. The obvious interest of the proprietor in letting his lands to the best advantage has gradually broken the force of these old feudal connections, and the hereditary occupants of the Highland estates are now ejected by the landlord, to make way for a more improved mode of cultivation, and for more profitable tenants. Under the old system, as many inhabitants were settled on the land as it could maintain; under the new system no more hands are maintained on it than can be profitably employed; and the superfluous labourers or tenants, who are thus removed from the spot which their families have possessed for centuries, naturally turn their views to America, where there are boundless tracts of unoccupied land ready to receive them. Their early habits and mode of life entirely disqualify them for mercantile business. Ejected from their hereditary possessions, they are in a manner outcasts in their native land, and, in search of some new place of rest, they voluntarily quit their kindred and their home.

Emigrations from the Highlands of Scotland.

The emigrations from the Highlands of Scotland have always kept pace with the progress of improvement, and from about the year 1773 they have been continued with little intermission. Of all those who were thus compelled to quit their native land, America became the natural asylum; and to different points of this extensive continent they were attracted by circumstances in a great measure accidental. The first emigrations were undertaken under all the disadvantages and anxiety of imperfect information; but these having succeeded, a more secure foundation was laid for future enterprises of the same nature, and the Highlanders who were disposed to emigrate naturally chose the spot where their friends were already settled. In this way they are scattered throughout different parts of the American continent. Some have formed settlements in the state of New York, on the Delaware, the Mohawk, and the Connecticut; while others have gone to Georgia and to North Carolina, or to the more northerly climate of Canada and Nova Scotia. Their choice of a settlement appears to have been dictated by the natural wish of being near their friends, by whose experience and advice they would be assisted through all the difficulties of a first establishment. A mode of conduct more rational, more calculated for social comfort and for ultimate success, can scarcely be imagined; and if the interest of the emigrant had been alone considered, no other plan would ever have been adopted.

Observations on Lord Se kirk's pl

The late Lord Selkirk appears to have viewed the decay of ancient manners in the Highlands, and the ejection of the unfortunate peasantry from their lands, with a deep and compassionate interest; and he assisted and advised them in their plans of emigration, and himself conducted and settled two bodies of emigrants in North America. But it is deeply to be regretted, that in the emigrations planned by Lord Selkirk, other views were mingled with the original and simple purpose of these expeditions. Instead of assisting the Highlanders in their own natural and rational plan of joining their friends already settled on the other side of the Atlantic, his purpose, as he himself states, was to detach them from those natural ties; to counteract the motives which induced them to follow their friends and relations, and to collect them into a new settlement, under the dominion of the mother country. After pointing out the strong inducements which the emigrants have to collect in particular spots, to which the presence of their friends and connections impart the attraction almost of another home, he observes, that, to overcome these motives, it is indispensable that "some strong inducement should be held out to the first party who will settle in the situation offered to them. To detached individuals," he continues, "it would be difficult to offer advantages sufficient to counterbalance the pleasure of being settled among friends, as well as the assistance they might expect from relations. But a considerable body of people connected by the ties of blood and friendship may have less aversion to try a new situation." Lord Selkirk objects to emigration where the adventurers are allowed to follow their own notions, and settle in detached bodies in different parts of the American territory, because it scatters the national resources, which he proposes to keep together, by inducing the emigrants to settle in the British colonies, "where," he observes, "they would be of national utility," and where all the peculiarities of their language and manners might be preserved. He seems also to imagine, that if the Highlanders were settled on the Canadian frontier, they would form an admirable outpost to guard the colony from the intrusion of American settlers, and from the worse plague of the American principles, of which he entertains a great dread, and against which he considers the inveterate loyalty of the Highlanders as an admirable barrier. In pursuance of those views, a colony of Highlanders was induced by Lord Selkirk to settle in Prince Edward's Island, in the Gulf of St Lawrence, where an establishment was formed, and where, in the course of about two years, a supply of subsistence was produced equal to the wants of the settlers. Another colony was afterwards conducted to the western parts of Upper Canada, and settled on Red River, where it encountered the most violent opposition from the deep-rooted jealousy of the *North-West Canadian Fur Company;* to counteract whose schemes Lord Selkirk purchased shares in the Hudson's Bay Company; and in the course of the rivalry which now took place, various acts of hostility and sanguinary outrage were committed. In one serious conflict which occurred, about twenty or thirty of Lord Selkirk's people lost their lives, and the settlement was nearly destroyed. From this calamity it slowly revived, and, by the accession of new settlers, its inhabitants are said to amount to about 500. In 1821, the Hudson's Bay Company and the North-West Company formed a coalition, which terminated their mutual hostilities.

To the plans of emigration set on foot by Lord Selkirk there is this strong and general objection, that they propose to accomplish objects in which the emigrant has not the most remote interest, and for which all the comfort, as well as the solid advantages, which he would derive from the intercourse of his relations and friends, are uselessly sacrificed. The sole purpose for which he quits his country is to procure a settlement in another on the most easy and advantageous terms; this is his only motive for embarking in so hazardous an enterprise; and whatever is unconnected with his ultimate prosperity and happiness is entirely foreign to the main object of his voyage. To settle among friends and relations, whose comfort and assistance is material to the emigrant, or in a country which has the benefit of a free and enlightened government, where he is sure of protection, and where, as much as possible, he may have all the helps of civilization to facilitate his progress, is wise and rational; and there is something unnatural, as well as revolting, in the notion of extinguishing all those social feelings which bind the emigrant to his friends and relations, and which revive, even on a foreign shore, the image of his native land. According to Lord Selkirk's plan, the emigrant is deprived of all those consolations; and he is tempted to try a new situation, for the vague and chimerical purpose of concentrating, for the benefit of the mother country, resources which would be otherwise scattered; or for the still more chimerical purpose of guarding the Canadian frontier from the inroad of American principles. These are political objects in which the emigrant has not the most remote interest. Formerly, the emigrants from the Highlands had almost the whole continent of North America open to their choice. They could settle among their countrymen and relations, amid the blessings of civilization and of regular government. According to Lord Selkirk's plan, they are thrown upon precisely the very worst portion of the American continent, withdrawn from the more genial climes of the South, exposed to the long rigours of a Canadian winter, and separated from their friends. The first body of emigrants who accompanied Lord Selkirk were settled on an island in the Gulf of St Lawrence, in a desolate spot, thirty miles from any habitation, in "circumstances scarcely more favourable," as he himself observes, "than if the island had been completely desert." His second colony was established on the continent, far to the westward of any settlement, and wholly without the precincts of civilization or regular government; and the fatal catastrophe by which it was overwhelmed is a suitable commentary on the original impolicy of choosing the desert for a settlement, and of relinquishing the protection of government, with all the other advantages of a more improved state of society. The happiness and comfort of the colonists, which is the fundamental principle of all colonization, was made subservient in those plans to other objects, in the highest degree absurd and chimerical; other interests were allowed to mingle with that great and radical interest; and useless hazards were incurred, hazards which were avoided so long as the emigrants were allowed to follow the sure and unerring instincts of their own individual prudence. (F.)

EMINENCE, in *Geography*, a little hillock or ascent above the level of the adjoining champaign country.

Eminence is also a title of honour given to cardinals. The decree of the pope, by which it was appointed that the cardinals should be addressed under the quality of *eminence*, bears date the 10th of January 1630. They then laid aside the titles of *illustrissimi* and *reverendissimi*, which they had before borne. The grand master of Malta was likewise addressed under the quality of *eminence*. The popes John VIII. and Gregory VII. gave the same title to the kings of France. The emperors have likewise borne it.

EMIR, a title of dignity amongst the Turks, signifying a prince. This title was first given to the caliphs; but when they assumed the title of sultans, that of emir remained to their children, as that of Cæsar among the Romans. At length the title came to be attributed to all who were judged to be descended from Mahommed by his daughter Fatima, and who consequently wear the green turban instead of the white. The Turks make an observation, that the emirs, before their fortieth year, are men of the greatest gravity, learning, and wisdom; but after this, if they are not great fools, they discover some signs of levity and stupidity. This is interpreted by the Turks as a sort of divine impulse in token of their birth and sanctity. The Turks also call the vizirs, pashas, or governors of provinces, by this name.

EMISSARY, in a political sense, a person employed by another to sound the opinions of people, spread certain reports, or act as a spy over other people's actions.

EMMANUEL, or Immanuel, a Hebrew word, which signifies "God with us." Isaiah (vii. 14), in that celebrated prophecy in which he declares to Ahaz the birth of the Messiah, who was to be born of a virgin, says, this child shall be called, and really be, Emmanuel, that is, *God with us.* The same prophet (viii. 8) repeats the same thing, whilst speaking of the enemy's army, which, like a torrent, was to overspread Judea. "The stretching out of his wings shall fill the breadth of thy land, O Emmanuel." The evangelist Matthew (i. 23) informs us, that this prophecy was accomplished in the birth of Christ, born of the virgin Mary; in whom the two natures, divine and human, were united, and so in this sense he was really Emmanuel, or God with us.

EMMERICH, a city of the Prussian Rhenish province of Julich-Cleeves, in the circle of Rees. It stands on the river Rhine, and contains two Catholic, a Lutheran, a Calvinist, and a Mennonite church, with 980 houses and 4450 inhabitants. It has linen and woollen manufactories, and enjoys considerable trade by the Rhine, and especially in leather. Long. 6. 7. 37. E. Lat. 51. 50. 17. N.

EMMIUS, Ubbo, born at Gretha in East Friesland in 1547, was a very learned professor, and chosen rector of the college of Norden in 1579. This seminary flourished exceedingly under his care; but it declined as visibly after he was ejected, in 1587, for refusing to subscribe the confession of Augsburg. The year afterwards he was made rector of the college of Leer; and when the city of Groningen confederated with the United Provinces, the magistrates appointed him rector of that college; which employment he filled with high reputation for nearly twenty years, until the college was erected into an university, when he became the first rector, and one of its chief ornaments by his lectures, till his infirmities prevented his public appearance. His wisdom was equal to his learning, so that the governor of Friesland and Groningen often consulted him, and seldom failed to follow his advice. He wrote, 1. *Opus Chronologicum*, Groningen, 1619, fol.; 2. *Vetus Græcia illustrata*, Leyden, 1626, 8vo; 3. *Rerum Frisicarum Historia*, Leyden, 1616, fol.; 4. *Historia Temporis nostri*, Groningen, 1732, 4to; and other works. He died in 1625.

EMMENAGOGUES, Εμμηναγωγα, in *Medicine*, such remedies as promote the menstrual discharge. They are thus called from εν, in, μην, month, αγω, *duco*, I lead, because the natural period of flowing is once a month.

EMOLLIENTS, in *Medicine* and *Pharmacy*, are such remedies as soften the asperity of the humours, and at the same time relax the rigidity of the solids.

EMOLUMENT is properly applied to the profits arising daily from an office or employment. The word is formed from the Latin *emolumentum*, which, according to some, primarily signifies the profits redounding to the miller from his mill. The patent, or other instrument, by which a person is preferred to an office, gives him a right to enjoy all the duties, honours, profits, and emoluments belonging thereto. *Emolument* is also used, with somewhat greater latitude, to signify profit or advantage in general.

EMOTION and PASSION are thus distinguished by Lord Kames, in his *Elements of Criticism*. "An internal motion or agitation of the mind, when it passeth away without desire, is denominated *an emotion;* when desire follows, the motion or agitation is denominated *a passion.* A fine face, for example, raiseth in me a pleasant feeling; if that feeling vanish without producing any effect, it is in proper language an *emotion;* but if the feeling, by reiterated views of the object, become sufficiently strong to occasion desire, it loses its name of emotion, and acquires that of *passion.* The same holds in all the other passions. The painful feeling raised in a spectator by a slight injury done to a stranger, being accompanied with no desire of revenge, is termed an emotion; but that injury raiseth in the stranger a stronger emotion, which being accompanied with desire of revenge, is a passion. External expressions of distress produce in the spectator a painful feeling, which being sometimes so slight as to pass away without any effect, is an emotion; but if the feeling be so strong as to prompt desire of affording relief, it is a passion, and is termed a *pity.* Envy is emulation in excess; if the exaltation of a competitor be barely disagreeable, the painful feeling is an emotion; if it produce desire to depress him, it is a passion."

EMOUY, AMOY, or HIAMEN, an island of China, near the south-east coast, belonging to the province of Fokien. It was formerly resorted to by Europeans before their commerce was restricted to Canton. It is about fifteen miles in circuit, and has a fort constructed between the island and the main. Here are several temples, one of them dedicated to the god Fo, with his statue of colossal size; and here also are the images of numerous other divinities, besides strange allegorical paintings. Long. 118. 22. E. Lat. 24. 30. N.

EMPALEMENT, an ancient punishment, which consisted in thrusting a stake through the fundament. The word comes from the French *empaler*, or the Italian *impalare;* or rather, both are derived from the Latin *palus*, a stake, and the preposition *in*, in or into. We find mention made of empaling in Juvenal. It was frequently practised in the time of Nero, and continues to be so in Turkey.

EMPEDOCLES, a celebrated philosopher and poet, was born at Agrigentum, a city in Sicily. He followed the Pythagorean philosophy, and admitted the doctrine of the metempsychosis. He constantly appeared with a crown of gold on his head, in order to maintain, by this outward pomp, the reputation which he had acquired of being a very extraordinary person. Yet Aristotle says that he was a great lover of liberty, extremely averse to state and command, and that he even refused a kingdom which was offered him. His principal work was a treatise in verse on the Nature and Principles of Things. Aristotle, Lucretius, and all the ancients, pronounce the most magnificent eulogiums on his poetry and eloquence. Empedocles taught rhetoric, and often alleviated the anxieties of his mind, as well as the pains of his body, with music. It is reported that his curiosity to visit the flames of the crater of Ætna proved fatal to him. Some maintain that he wished it to be believed that he was a god, and, in order that his death might be unknown, threw himself into the crater, and perished in the flames. If such were his expectations, however, they were frustrated; for the volcano, by throwing up one of his sandals, discovered to the world that Empedocles had perished by fire. Others report that he lived to an extreme old age, and was drowned in the sea about 440 years before the Christian era.

EMPEROR (*imperator*), among the ancient Romans, signified a general of an army, who, for some extraordinary success, had been complimented with this appellation. Thus Augustus, having obtained no less than twenty famous victories, was as often saluted with the title *emperor;* and Titus was denominated *emperor* by his army after the reduction of Jerusalem. Subsequently it came to denominate an absolute monarch or supreme commander of an empire. In this sense Julius Cæsar was called *emperor;* the same title descended with the dignity to Octavianus Augustus, Tiberius, and Caligula; and afterwards it became elective. In strictness the title *emperor* does not, and cannot, add any thing to the rights of sovereignty; its effect is only to give precedence and pre-eminence above other sovereigns; and as such, it raises those invested with it to the summit of all human greatness. In the east, the title and quality of emperor are more frequent than in Europe; thus, the sovereign princes of China, Japan, Mogul, &c. are all emperors. In Europe, the first who bore the title was Charlemagne, upon whom it was conferred by Pope Leo III. though he had all the power before.

EMPHASIS, in *Rhetoric*, a particular stress of the voice and action, laid on such parts or words of the oration as the orator wants to enforce upon his audience.

EMPHYSEMA, in *Surgery*, a windy tumour, generally occasioned by a fracture of the ribs, and formed by the air insinuating itself, by a small wound, between the skin and muscles, into the substance of the cellular or adipose membrane, and then spreading itself up to the neck, head, belly, and other parts, much in the same manner as butchers blow up their veal.

EMPIRE (*imperium*), in political geography, a large extent of land, under the jurisdiction or government of an emperor. In ancient history we read of four great monarchies or empires, namely, that of the Babylonians, Chaldeans, and Assyrians; that of the Medes and Persians; that of the Greeks; and that of the Romans. The first subsisted from the time of Nimrod, who founded it in the year of the world 1800, according to the computation of Usher, till that of Sardanapalus their last king in 3257, and consequently lasted above 1450 years. The empire of the Medes commenced under Arbaces, in the year of the world 3257, was united to that of the Babylonians and Persians under Cyrus, in 3468, and closed with the death of Darius Codomannus in 3674. The Grecian empire lasted only during the reign of Alexander the Great, beginning in the year of the world 3674, and terminating with the death of this conqueror in 3681, his conquests having been divided amongst his captains. The Roman empire commenced with Julius Cæsar, when he was made perpetual dictator, in the year of the city 708, and of the world 3956, forty-eight years before Christ. The seat of the empire was removed to Byzantium by Constantine, in the year of our Lord 334; and the East and West were then united under the title of the Roman empire, till the Romans proclaimed Charlemagne emperor, in the year 800. From this epoch the East and West formed two separate empires. That of the East, governed by Greek emperors, commenced in the year 302; and being gradually weakened, terminated under Constantine Palæologus in 1453. The western empire was afterwards known by the appellation of the empire, or German empire. Antiquaries distinguish between the medals of the Upper and Lower Empire. The curious only value those of the Upper Empire, which commenced with Cæsar or Augustus, and ended in the year of Christ 260. The Lower Empire comprehended near 1200 years, reckoning downwards till the destruction of Constantinople in 1453. Two ages, or periods, of the Lower Empire are usually distinguished; the first beginning where the Upper ends, namely, with Aurelian, and terminating with Anastasius, including 200 years; and the second beginning with Anastasius, and ending with the Palæologi, which includes 1000 years.

Empire, or *The Empire*, used absolutely and without any addition, signifies the empire of Germany, which is also called in juridical acts and laws the holy Roman empire. It had its beginning at the commencement of the ninth century, when Charlemagne was created first emperor by Pope Leo III. who put the crown on his head in St Peter's church on Christmas day in the year 800.

EMPIRIC, an appellation given to those physicians who conduct themselves wholly by their own experience, or by arbitrary modes, without studying physic in a regular way. Some even use the term in a still worse sense, for a quack who prescribes at random, without being at all acquainted with the principles of the healing art.

EMPRESS, the spouse of an emperor, or a woman who governs an empire.

EMPROSTHOTONOS, a species of convulsion, in which the head bends forward.

EMPYREUM, a term used by divines for the highest heaven, where the blessed enjoy the beatific vision. The word is formed of εν, *in*, and πυρ, *fire*, because of its splendour.

EMPYREUMA, in *Chemistry*, signifies a very disagreeable smell produced from burnt oils. It is often perceived in the distillation of animal as well as vegetable substances, when these are exposed to a quick fire.

EMS, a market-town of the duchy of Nassau, in Germany. It stands on the river Lahn, which runs to the Rhine. It is a celebrated place, on account of the warm springs, which are much frequented at the proper season, as well for cure as for relaxation and pleasure. There are no fewer than thirty-three warm baths. The water is of the heat of 37° of Reaumur. The country around is wild and romantic. The regular residents are only about 350.

EMULATION, a generous ardour kindled by the praiseworthy example of others, which impels us to imitate, to rival, and, if possible, to excel them. This passion involves in it esteem of the person whose attainments or conduct we emulate, and of the qualities or actions in which we emulate him, and a desire of resemblance, together with a joy springing from the hope of success. The word comes originally from the Greek ἁμιλλα, a *dispute* or *contest*; whence the Latin *æmulus*, and thence our *emulation*.

EMULGENT or Renal Arteries, those which supply the kidneys with blood; being sometimes single, sometimes double, on each side.

EMUNCTORY, in *Anatomy*, a general term for all those parts which serve to carry off the excrementitious parts of the blood and other humours of the body. Such are the kidneys, bladder, and most of the glands.

ENALLAGE, in *Grammar*, is when one word is substituted for another of the same part of speech: a substantive for an adjective; as *exercitus victor*, for *victoriosus*; *scelus*, for *scelestus*: a primitive for a derivative; as *Dardana arma*, for *Dardania*: an active for a passive; as *nox humida cælo precipitat*, for *præcipitatur*; and so on.

ENAMEL, in general, is a vitrified matter, betwixt the parts of which is dispersed some unvitrified matter; and hence enamel ought to have all the properties of glass except transparency.

Enamels have for their basis a pure crystal glass or frit, ground up with a fine calx of lead and tin prepared for the purpose, with the addition usually of white salt of tartar. These ingredients baked together are the matter of all enamels, which are made by adding colours to this matter, and melting or incorporating them together in a furnace.

For white enamel, Neri (*De Arte Vitriar.*) directs only manganese to be added to the matter which constitutes the basis; for azure, zaffer mixed with calx of brass; for green, calx of brass with scales of iron, or with crocus martis; for black, zaffer with manganese or with crocus martis, or manganese with tartar; for red, manganese, or calx of copper and red tartar; for purple, manganese with calx of brass; for yellow, tartar and manganese; and for violet-coloured enamel, manganese with thrice-calcined brass.

In making these enamels, the following general cautions are necessary to be observed: 1. That the pots must be glazed with white glass, and must be such as will bear the fire. 2. The matter of enamels must be very nicely mixed with the colours. 3. When the enamel is good, and the colour well incorporated, it must be taken from the fire with a pair of tongs. 4. The general way of making the coloured enamel is this: Powder, sift, and grind all the colours very nicely, and first mix them with one another, and then with the common matter of enamels; next set them in pots in a furnace, and when they are well mixed and incorporated, cast them into water; when dry, set them in a furnace again to melt; and when melted, take a proof of the enamel. If too deep coloured, add more of the common matter of enamels; and if too pale, add more of the colours.

Enamels are used either in counterfeiting or imitating precious stones, and in painting in enamel; or by enamellers, jewellers, and goldsmiths, in gold, silver, and other metals. The first two kinds are usually prepared by the workmen themselves who are employed in these arts; that used by jewellers and others is brought chiefly from Venice or Holland, in little cakes of different sizes, commonly about four inches diameter, having the mark of the maker struck upon it with a puncheon.

ENAMELLING, the art of laying enamel upon metals, as gold, silver, or copper, and of melting it on the fire, or of making divers curious works in it by means of a lamp. It signifies also to paint in enamel.

The method of painting in Enamel. This is performed on plates of gold or silver, and most commonly of copper, Enamelling.

enamelled with the white enamel, on which painting is executed with colours which are melted in the fire, where they take a brightness and lustre like that of glass. This painting is the most prized of all for its peculiar brightness and vivacity, which is permanent, the force of its colours not being liable to be effaced or sullied with time, as in other painting, and continuing always as fresh as when it came out of the workmen's hands. This method of painting is usual in miniature; but it is the more difficult the larger it is, by reason of certain accidents to which it is liable in the operation. Enamelling should only be practised on plates of gold, the other metals being less pure; copper, for instance, scales with the application, and yields fumes, and silver turns the yellow white. Nor must the plate be made flat; for in such case the enamel cracks; to avoid which accident the plates are usually forged a little round or oval, and not too thick. The plate being well and evenly forged, the operation is usually commenced by laying on a couch of white enamel (as we observed above) on both sides, which prevents the metal from swelling and blistering; and this first layer serves for the ground of all the other colours. The plate being thus prepared, the next step is to draw out exactly the subject to be painted with red vitriol, mixed with oil of spike, marking all parts of the design very lightly with a small pencil. After this, the colours (which must be previously ground with water in a mortar of agate extremely fine, and mixed with oil of spike somewhat thick) are to be laid on, observing the mixtures and colours which agree to the different parts of the subject; for which purpose it is necessary to understand painting in miniature. But here the workmen must be very cautious as to the quality of the oil of spike he employs to mix his colours with, for it is very subject to adulteration.

Great care must likewise be taken that the least dust imaginable mix not with the colours while the artist is either painting or grinding them; for the smallest speck worked up with the colour, when the work comes to be put into the reverberatory to be made red hot, will leave a hole, and so deface the performance.

When the colours are all laid, the painting must be gently dried over a slow fire to evaporate the oil, and the colours afterwards melted to incorporate them with the enamel, making the plate red hot in a fire like that which the enamellers use. Afterwards that part of the painting must be gone over again which the fire has in any degree effaced, strenghening the shade and colours, and committing it a second time to the fire, observing the same method as before, which is to be repeated till the work be finished.

Method of ENAMELLING *by the lamp.* Most enamelled works are wrought at the fire of a lamp, in which, instead of oil, is put melted horse-grease, which they called *caballine oil.* The lamp, which is of copper, or white iron, consists of two pieces; in one of which is a kind of oval plate, six inches long and two inches high, in which are put the oil and the cotton; whilst the other part, called the *box*, in which the lamp is inclosed, serves only to receive the oil which boils over by the force of the fire. This lamp, or, where several artists work together, two or more lamps, are placed on a table of proper height, under which, about the middle of its height, is a double pair of organ-bellows, which one of the workmen moves up and down with his foot to quicken the flame of the lamps, which by this means is excited to an incredible degree of vehemence. Grooves made with a gauge in the upper part of the table, and covered with parchment, convey the wind of the bellows to a pipe of glass before each lamp; and in order that the enamellers may not be incommoded with the heat of the lamp, every pipe is covered at six inches distance with a little tin plate, fixed into the table by a wooden handle. When the works do not require a long blast, the workmen only use a glass pipe, into which they blow with their mouth.

Encænia
||
Encaustic
Painting

It is incredible to what a degree of fineness and delicacy the threads of enamel may be drawn at the lamp. Those which are used in making false tufts of feathers are so fine that they may be wound on a reel like silk or thread. The fictitious jets of all colours used in embroideries are also made of enamel, and that with so much art, that every small piece has its hole to pass the thread through with which it is sewed. These holes are made by blowing them into long pieces, which are afterwards cut with a proper tool.

It is seldom that the Venetian or Dutch enamels are used alone; they are commonly melted in an iron ladle, with an equal part of glass or crystal; and when the two matters are in perfect fusion, the mass is drawn out into threads of different sizes, according to the nature of the work. The workmen take it out of the ladle while liquid with two pieces of broken tobacco-pipes, which they extend from each other at arm's length. If the thread is required still longer, then another workman holds one end, and continues to draw it out, while the first holds the enamel to the flame. Those threads, when cold, are cut into whatever lengths the workman thinks fit, but commonly from ten to twelve inches; and as they are all round, if they are required to be flat, they must, while hot, be drawn through a pair of pincers. They have also another iron instrument in the form of pincers for drawing out the enamel by the lamp when it is to be worked and disposed in figures. Lastly, they have glass tubes of various sizes, which serve to blow the enamel into various figures, and preserve the necessary vacancies therein, as also to spare the stuff, and form the contours. When the enameller is at work, he sits before the lamp with his foot on the step which moves the bellows; and holding in his left hand the work to be enamelled, or the brass or iron wires on which the figures are to be formed, he directs with his right the enamel thread, which he holds to the flame with a management and patience equally surprising. There are few things which cannot be made or represented with enamel; and some figures are as well finished as if done by the most skilful carvers.

ENCÆNIA, the name of three several festivals celebrated by the Jews in memory of the dedication, or rather purification, of the temple of Judas Maccabæus, Solomon, and Zorobbabel. This term is likewise used in church history for the dedication of Christian churches.

ENCAUSTIC and ENCAUSTUM, the same with enamelling and enamel.

ENCAUSTIC *Painting*, a method of painting made use of by the ancients, in which wax was employed to give a gloss to their colours, and to preserve them from injury by air or moisture.

This ancient art, after having been long lost, was restored by Count Caylus, a member of the Academy of Inscriptions in France; and the method of painting in wax was announced to the Academy of Painting and Belles-Lettres in the year 1753; but M. Bachelier, the author of a treatise *De l'Histoire et du Secret de la Peinture en Cire*, had actually painted a picture in wax in 1749; and he was the first who communicated to the public the method of performing the operation of inustion, which is the principal characteristic of the encaustic painting. The count kept his method a secret for some time, contenting himself with exhibiting a picture at the Louvre in 1754, representing the head of Minerva, painted in the manner of the ancients, which excited the curiosity of the public, and was very much admired. In the interval of suspense, several attempts were made to recover the ancient method of painting. The first scheme adopted was that of melting wax and oil of turpentine together, and using this composition as a vehicle for mixing and laying on the colours. But this method did not explain Pliny's meaning, as in this way of managing it the wax is not burnt. In another attempt, which was much more agreeable to the historian's description of encaustic painting, the wax was melted with strong lixivium of salt of tartar, and with this the colours were ground. When the picture was finished, it was gradually presented to the fire, so as to melt the wax, which was thus diffused through all the particles of the colours, so that they were fixed to the ground, and secured from the access of air or moisture. But the method of Count Caylus is much more simple. The cloth or wood which he designed as the basis of his picture is waxed over by only rubbing it simply with a piece of bees-wax; the wood or cloth, stretched on a frame, being held horizontally over, or perpendicularly before a fire, at such a distance that the wax might gradually melt whilst it is rubbed on, diffuse itself, penetrate the body, and fill the interstices of the texture of the cloth, which when cool is fit to be painted upon; but as water colours, or those which are mixed up with common water, will not adhere to the wax, the whole picture is to be first rubbed over with Spanish chalk or white, and then applied to it. When the picture is dry, it is put near the fire, by means of which the wax melts, and absorbs all the colours.

Mr J. H. Muntz, in a treatise on this subject, has proposed several improvements in the art of encaustic painting. When the painting is on cloth, he directs it to be prepared by stretching it on a frame, and rubbing one side several times over with a piece of bees-wax, or virgin wax, till it be covered with a coat of wax of considerable thickness. In fine linen this is the only operation necessary previous to painting; but coarse cloth must be rubbed gently on the unwaxed side with a pumice-stone, to take off all those knots which would prevent the free and accurate working of the pencil. Then the subject is to be painted on the unwaxed side with colours prepared and tempered with water; and when the picture is finished, it must be brought near the fire, that the wax may melt and fix the colours. This method, however, can only be applied to cloth or paper, through the substance of which the wax may pass; but in wood, stone, metals, or plaster, the former method of Count Caylus must be observed.

Mr Muntz has also discovered a method of forming grounds for painting with crayons, and fixing these, as well as water-colours employed with the pencil. On the unwaxed side of a linen cloth, stretched and waxed as before, lay an even and thick coat of the colour proper for the ground; having prepared this colour by mixing some proper pigment with an equal quantity of chalk, and tempering them with water. When the colour is dry, bring the picture to the fire, in order that the wax may melt, pass through the cloth, and fix the ground. An additional quantity of wax may be applied to the back of the picture, if that which was first rubbed on should not be sufficient for the body of colour; but as this must be laid on without heat, the wax should be dissolved in oil of turpentine, and applied with a brush, and the canvass should be again exposed to the fire, that the fresh supply of wax may pass through the cloth, and be absorbed by the colour; and thus a firm and good body will be formed for working on with the crayons. If cloth and paper are joined together, the cloth must be first fixed to the straining frame, and then the paper must be pasted to it with a composition of paste made with wheaten flour, or starch and water, and about a twelfth part of its weight of common turpentine. The turpentine must be added to the paste when it is almost sufficiently boiled, and the composition well stirred, and left to simmer over the fire for five or six minutes. Let wax be dissolved in oil of turpentine to the consistence of a thin paste; and when the cloth and paper are dry, let them be held near a fire, and with a brush lay a coat of the wax and turpentine on both sides of the joined cloth and paper, in such a degree of thickness that both surfaces may shine throughout without any appearance of dull spots. Then expose the cloth to the fire, or to the sun, by which means the oil will evaporate, and the wax become solid, and be fit to receive any composition of colour for a ground, which is to be laid on as above directed in the case of cloth without paper.

Almost all the colours which are used in oil painting may also be applied in the encaustic method. Mr Muntz objects, indeed, to brown, light pink, and unburnt *terra di Sienna*, because these, on account of their gummy or stony texture, will not admit such a cohesion with the wax as will properly fix them; but other colours which cannot be admitted in oil painting, as red lead, red orpiment, crystals of verdigris, and red precipitate of mercury, may be used here. The crayons used in encaustic painting are the same with those used in the common way of crayon painting, excepting those which in their composition have too great tenacity; and the method of using them is the same in both cases.

The encaustic painting has many peculiar advantages: though the colours have not the natural varnish or shining which they acquire with oil, they have all the strength of paintings in oil, and all the airiness of water-colours, without partaking of the apparent character or defects of either. They may be looked at in any light and in any situation, without any false glare; the colours are firm, and will bear washing; and a picture, after having been smoked, and then exposed to the dew, becomes as clean as if it had been but just painted. It may also be retouched at pleasure without any detriment to the colours; for the new colours will unite with the old ones, without spots, as is the case in common size painting: nor is it necessary to rub the places to be touched with oil, as in oil pictures; it is not liable to crack, and is easily repaired if it should chance to suffer any injury. The duration of this painting is also a very material advantage; the colours are not liable to fade and change; no damp can affect them, nor any corrosive substance injure them; nor can the colours fall off in shivers from the canvass. However, notwithstanding all these and other advantages enumerated by the Abbé Mazeas and Mr Muntz, this art has not yet been much practised. Many of these properties belong to a much higher species of encaustic painting afterwards discovered in England, the colours of which are fixed by a very intense heat; nor are the colours or grounds on which they are laid liable to be dissolved or corroded by any chemical menstruum, nor, like the glassy colours of enamel, to run out of the drawing on the fire. What this method consists in will appear from the following account communicated in a letter from Josiah Colebrook to the Earl of Macclesfield, president of the Royal Society in 1756.

"The art of painting with burnt wax," says he, "has long been lost to the world. The use of it to painters in the infancy of the art of painting was of the utmost consequence. Drying oil being unknown, they had nothing to preserve their colours entire from the injury of damps and the heat of the sun. A varnish of some sort was therefore necessary; but they being unacquainted with distilled spirits, could not, as we now do, dissolve gums to make a transparent coat for their pictures. This invention therefore of burnt wax supplied that defect to them; and with this manner of painting the chambers and other rooms in the houses were furnished. This Pliny calls *encaustum*, and we *encaustic painting*.

"The following experiments, which I have the honour to lay before your lordship and the society, were occasioned by the extract of a letter from the Abbé Mazeas, translated by Dr Parsons, and published in the second part of the forty-ninth volume of the *Philosophical Transactions*, No. 100, concerning the ancient method of painting with burnt wax revived by Count Caylus.

"The count's method was, 1. To rub the cloth or board designed for the picture simply over with bees-wax: 2. To lay on the colours mixed with common water; but as the colours will not adhere to the wax, the whole picture was first rubbed over with Spanish chalk, and then the colours are used: 3. When the picture is dry it is put near the fire, whereby the wax melts, and absorbs all the colours.

"*Exp.* 1. A piece of oak board was rubbed over with bees-wax, first against the grain of the wood, and then with the grain, to fill up all the pores that remained after it had been planed, and afterwards was rubbed over with as much dry Spanish white as could be made to stick on it. This, on being painted (the colours mixed with water only), so clogged the pencil, and mixed so unequally with the ground, that it was impossible to make an even outline, but was so much thicker in one part than another, that it would not bear so much as the name of painting; neither had it any appearance of a picture. However, to pursue the experiment, this was put at a distance from the fire, on the hearth, and the wax melted by slow degrees; but the Spanish white, though laid as smooth as so soft a body would admit before the colour was laid on, on melting the wax into it, was not sufficient to hide the grain of the wood, nor show the colours by a proper whiteness of the ground; the wax, in rubbing on the board, was unavoidably thicker in some parts than in others, and the Spanish white the same.

"To obviate the inequality of the ground in the first experiment,

"*Exp.* 2. A piece of old wainscot (oak board) one fourth of an inch thick, which, having been part of an old drawer, was not likely to shrink on being brought near the fire. This was smoothed with a fish skin, made quite warm before the fire, and then, with a brush dipped in white wax melted in an earthen pipkin, smeared all over, and applied to the fire again. That the wax might be equally thick in all parts of the board, a ground was laid (on the waxed board) with levigated chalk mixed with gum-water (viz. gum-arabic dissolved in water). When it was dry, I painted it with a kind of landscape; and pursuing the method laid down by Count Caylus, brought it gradually to the fire. I fixed the picture on a fire screen, which would preserve the heat, and communicate it to the back part of the board. This was placed first at the distance of three feet from the fire, and brought forwards by slow degrees till it came within one foot of the fire, which made the wax swell and bloat up the picture; but as the chalk did not absorb the wax, the picture fell from the board, and left it quite bare.

"*Exp.* 3. I mixed three parts white wax, and one part white resin, hoping the tenacity of the resin might preserve the picture. This was laid on a board heated with a brush, as in the former; and the ground was chalk prepared as before. This was placed horizontally on an iron box charged with a hot heater, shifting it from time to time, that the wax and resin might penetrate the chalk, and hoping from this position that the ground, bloated by melting the wax, would subside into its proper place; but this, like the other, came from the board, and would not at all adhere.

"*Exp.* 4. Prepared chalk four drams, white wax, white resin, of each a dram, burnt alabaster half a dram, were all powdered together and sifted, mixed with spirit of molasses instead of water, and put for a ground on a board smeared with wax and resin, as in *Exp.* 3. This was also placed horizontally on a box-iron, as the former. The picture blistered, and was cracked all over; and though removed from the box-iron to an oven moderately heated, in the same horizontal position, it would not subside nor become smooth. When it was cold, I took an iron spatula made warm, and moved it gently over the surface of the picture, as if I were to spread a plaster. (This thought occurred from the board being prepared with wax and resin, and the ground having the same materials in its composition, the force of the spatula might make them unite). This succeeded so well as to reduce the surface to a tolerable degree of smoothness; but as the ground was broke off in many places, I repaired it with flake white, mixed up with the yolk of an egg and milk, and repainted it with molasses spirit, instead of water, and then put it into an oven with a moderate degree of heat. In this I found the colours fixed, but darker than when it was at first painted; and it would bear being washed with water, not rubbed with a wet cloth.

"*Exp.* 5. A board, that had been used in a former experiment, was smeared with wax and resin, of each equal parts; was wetted with molasses spirit to make whitening or Spanish white, mixed with gum water, adhere. This when dry was scraped with a knife to make it equally thick in all places. It was put into a warm oven to make the varnish incorporate partly with the whitening before it was painted, and it had only a small degree of heat; water was only used to mix the colours. This was again put into an oven with a greater degree of heat; but it flaked off from the board: whether it might be owing to the board's having had a second coat of varnish, the first having been scraped and melted of, and that the unctuous parts of the wax had so entered its pores that it would not retain a second varnish, I cannot tell.

"*Exp.* 6. Having miscarried in these trials, I took a new board, planed smooth, but not polished either with a fish skin or rushes. I warmed it, and smeared it with wax only; then took *cimolia* (tobacco-pipe clay) divested of its sand, by being dissolved in water and poured off, leaving the coarse heavy parts behind. After this was dried and powdered, I mixed it with a small quantity of the yolk of an egg and cow's milk, and made a ground with this on the waxed board. This I was induced to try, by knowing that the yolk of an egg will dissolve almost all unctuous substances, and make them incorporate with water; and I apprehended that a ground thus prepared would adhere so much the more firmly to the board than the former had done as to prevent its flaking off. The milk, I thought, might answer two purposes; first, by uniting the ground with the wax; and, secondly, by answering the end of size or gum-water, and prevent the colours from sinking too deep into the ground, or running one into another. When the ground was near dry, I smoothed it with a pallet knife, and washed it with milk and egg where I had occasion to make it smooth and even. When dry, I painted it, mixing the colours with common water. This, on being placed horizontally in an oven only warm enough to melt the wax, flaked from the board; but held so much better together than any of the former that I pasted part of it on paper.

"*Exp.* 7. Flake-white, or the purest sort of white-lead, mixed with egg and milk crumbled to pieces in the oven, put on the waxed board, as in the last experiment.

"The bad success which had attended all the former experiments led me to consider of what use the wax was in this kind of painting, and it occurred to me that it was only as a varnish, to preserve the colours from fading.

"In order to try this,

"*Exp.* 8. I took what the bricklayers call *fine stuff* or *putty;* to this I added a small quantity of burnt alabaster, to make it dry; this it soon did in the open air; but before I put on any colours, I dried it gently by the fire, lest the colours should run. When it was painted, I warmed it gradually by the fire, to prevent the ground from cracking, till it was very hot. I then took white wax three parts, white resin one part; melted them in an earthen pipkin, and with a brush spread them all over the painted board, and kept it close to the fire in a perpendicular situation, that what wax and resin the plaster would not absorb might drop off. When it was cold, I found the colours were not altered, either from the heat of the fire, or passing the brush over them. I then rubbed it with a soft linen cloth, and thereby procured a kind of gloss, which I afterwards increased by rubbing it with a hard brush; which was so far from scratching or leaving any marks on the picture, that it became more smooth and polished by it.

"After I had made all the foregoing experiments, in conversation with my honoured and learned friend Dr Kidby, a fellow of this society, I said I had been trying to find out what the encaustic painting of the ancients was; upon which he told me, that there was a passage in Vitruvius *De Architectura* relative to that kind of painting, and was so good as to transcribe it for me from the 7th book, chap. 9, *De minii temperatura.* Vitruvius's words are: *At si quis subtilior fuerit, et voluerit expolitionem miniaceam suum colorem retinere, cum paries expolitus et aridus fuerit, tunc ceram Punicam liquefactam igni, paulo oleo temperatam, seta inducat, deinde postea carbonibus in ferreo vase compositis, eam ceram apprime cum pariete, calefaciendo sudore cogat, fiatque ut peræquetur, deinde cum candela linteisque puris subigat, uti signa marmorea nuda curantur. Hæc autem καυσις Græce dicitur. Ita obstans ceræ Punicæ lorica non patitur, nec lunæ splendorem, nec solis radios lambendo eripere ex his politionibus colorem.*

"Which I thus translate: 'But if any one is more wary, and would have the polishing [painting] with vermilion hold its colour, when the wall is painted and dry, let him take Carthaginian [Barbary] wax, melted with a little oil, and rub it on the wall with a hair pencil; and afterwards let him put live coals into an iron vessel [chafing-dish], and hold it close to the wax, when the wall, by being heated, begins to sweat; then let it be made smooth; afterwards let him rub it with a candle and clean linen rags, in the same manner as they do the naked marble statues. This the Greeks called καυσις. The coat of Carthaginian wax thus put on is so strong, that it neither suffers the moon by night, nor the sun-beams by day, to destroy the colour.'

"Being satisfied, from this passage in Vitruvius, that the manner of using wax in *Exp.* 8 was right, I was now to find if the wax-varnish, thus burnt into the picture, would bear washing. But here I was a little disappointed; for rubbing one corner with a wet linen cloth, some of the colour came off; but washing it with a soft hair-pencil dipped in water, and letting it dry without wiping, the colour stood very well.

"A board painted as in *Exp.* 8 was hung in the most smoky part of a chimney for a day, and exposed to the open air in a very foggy night. In the morning the board was seemingly wet through, and the water ran off the picture. This was suffered to dry without wiping: and the picture had not suffered at all from the smoke or the dew, either in the ground or the colours; but when dry, by rubbing it, first with a soft cloth, and afterwards with a brush, it recovered its former gloss.

"Suspecting that some tallow might have been mixed with the white wax I had used, which might cause the colours to come off on being rubbed with a wet cloth, I took yellow wax which had been melted from the honeycomb in a private family, and consequently not at all adulterated: to three parts of this I added one part resin, and melted them together.

"*Exp.* 9. Spanish white, mixed with fish glue, was put for a ground on a board, and painted with water-colours only. The board was made warm; and then the wax and resin were put on with a brush, and kept close to the fire till the picture had imbibed all the varnish, and looked dry. When it was cold, I rubbed it first with a linen cloth, and then polished it with a hard brush.

"In these experiments I found great difficulties with regard to colours. Many water-colours being made from the juices of plants, have some degree of an acid in them; and these, when painted on an alkaline ground, as chalk, whitening, *cimolia,* and plaster, are totally changed in their colours, and from green become brown; which contributes much to make the experiments tedious. I would therefore advise the use of mineral or metallic colours for this sort of painting, as most likely to preserve their colour: for although I neutralized Spanish white, by fermenting it with vinegar, and afterwards washed it very well with water, it did not succeed to my wish.

"These experiments, and this passage from Vitruvius, will in some measure explain the obscurity of part of that passage in Pliny which Dr Parsons, in his learned comment on the encaustic painting with wax, seems to despair of.

"*Ceris pingere* was one species of encaustic painting. Ενκαυστον, *inustum,* may be translated, "forced in by the means of fire; burnt in:" for whatever is forced in by the help of fire can be rendered into Latin by no other significant word that I know of but *inustum.* If this is allowed me, and I think I have the authority of Vitruvius (a writer in the Augustan age) for it, who seems to have wrote from his own knowledge, and not like Pliny, who copied from others much more than he knew himself, the difficulty with regard to this kind of painting is solved, and the encaustic with burnt wax recovered to the public.

"What he means by the next kind he mentions, *in ebore cestro, id est viriculo,* I will not attempt to explain at present.

"The ship-painting is more easily accounted for, the practice being in part continued to this time; and is what is corruptly called *breaming,* for brenning or burning.

"This is done by reeds set on fire, and held under the side of a ship till it is quite hot; then resin, tallow, tar, and brimstone, melted together, and put on with a hair-brush while the planks remain hot, make such a kind of paint as Pliny describes; which, he says, *nec sole, nec sale ventisque corrumpitur.* As they were ignorant of the use of oil painting, they mixed that colour with the wax, &c. which they intended for each particular part of the ship, and put it on in the manner above described.

"In the pictures painted for these experiments, and now laid before your lordship and the society, I hope neither the design of the landscape, nor the execution of it, will be so much taken into consideration as the varnish, which was the thing wanted in this inquiry: and I think that will evince that the encaustic painting with burnt wax is fully restored by these experiments; and, though not a new invention, yet having been lost for so many ages, and now applied further, and to other purposes, than it was by Vitruvius, who confined it to vermilion only, may also amount to a new discovery, the use of which may be a means of preserving many curious drawings to posterity; for this kind of painting may be on paper, cloth, or any

Encaustic Painting.

other substance that will admit a ground to be laid on it. The process is very simple, and is not attended with the disagreeable smell unavoidable in oil-painting, nor with some inconveniences inseparable from that art; and as there is no substance we know more durable than wax, it hath the greatest probability of being lasting."

Still, however, there seem to have been some defects or inconveniences attending these and other subsequent attempts; for we find the ancient or some similar method of painting in wax remaining a desideratum upwards of twenty-five years after the publication of the preceding experiments; when in 1787 a method was communicated to the Society of Arts by Miss Greenland, for which she was rewarded with a prize. The ground of her information she had received at Florence, through the acquaintance of an amateur of painting, who procured her the satisfaction of seeing some paintings in the ancient Grecian style, executed by Signora Parenti, a professor at that place, who had been instructed by a Jesuit at Pavia, the person who had made the greatest discoveries in that art. Miss Greenland's friend knowing she was fond of painting, informed her what were the materials the paintress used, but could not tell her the proportions of the composition; however, from her anxiety to succeed in such an acquisition, she made various experiments, and at last obtained such a knowledge of the quantities of the different ingredients as to begin and finish a picture, which she afterwards presented to the society for their inspection.

Her method is as follows: "Take an ounce of white wax, and the same weight of gum mastich powdered. Put the wax in a glazed earthen vessel over a very slow fire; and when it is quite dissolved, strew in the mastich, a little at a time, stirring the wax continually until the whole quantity of gum is perfectly melted and incorporated: then throw the paste into cold water, and when it is hard, take it out of the water, wipe it dry, and beat it in one of Mr Wedgwood's mortars, observing to pound it at first in a linen cloth, to absorb some drops of water that will remain in the paste, and would prevent the possibility of reducing it to a powder, which must be so fine as to pass through a thick gauze. It should be pounded in a cold place, and but a little while at a time, as after long beating the friction will in a degree soften the wax and gum, and, instead of their becoming a powder, they will return to a paste.

"Make some strong gum-arabic water; and when you paint, take a little of the powder, some colour, and mix them together with the gum water. Light colours require but a small quantity of the powder, but more of it must be put in proportion to the body and darkness of the colours; and to black there should be almost as much of the powder as colour.

"Having mixed the colours, and no more than can be used before they grow dry, paint with fair water, as is practised in painting with water colours, a ground on the wood being first painted of some proper colour, prepared in the same manner as is described for the picture; walnut tree and oak are the sorts of wood commonly made use of in Italy for this purpose. The painting should be very highly finished, otherwise, when varnished, the tints will not appear united.

"When the painting is quite dry, with rather a hard brush, passing it one way, varnish it with white wax, which is put into an earthen vessel, and kept melted over a very slow fire till the picture is varnished, taking great care the wax does not boil. Afterwards hold the picture before a fire, near enough to melt the wax, but not make it run; and when the varnish is entirely cold and hard, rub it gently with a linen cloth. Should the varnish blister, warm the picture again very slowly, and the bubbles will subside. When the picture is dirty, it need only be washed with cold water."

Enceinte || Endian.

The opinion given by the society upon the above is, "The method made use of by Miss Greenland provides against all inconveniences; and the brilliancy of the colours in the picture painted by her, and exhibited to the society, fully justifies the opinion, that the art of painting in wax, as above described, highly merited the reward of a gold pallet voted to her on this occasion."

ENCEINTE, in *Fortification*, is the interior wall or rampart which surrounds a place, sometimes composed of bastions or curtains, either faced or lined with brick or stone, or only made of earth. The enceinte is sometimes only flanked by round or square towers, which is called a *Roman wall*.

ENCEPHALI, in *Medicine*, worms generated in the head, where they cause so great pain as sometimes to occasion distraction.

ENCHASING, INCHASING, or *Chasing*, the art of enriching and beautifying gold, silver, and other metal work, by some design or figures represented thereon in bas-relief. It is performed by punching or driving out the metal, in order to form a figure, from withinside, so as to stand out prominent from the plane or surface of the metal. In order to this, a number of fine steel blocks or puncheons of divers sizes are provided; and the design being drawn on the surface of the metal, the inside is applied to the heads or tops of these blocks, directly under the lines or parts of the figures; then the metal, sustained by the block, being struck by a hammer, yields, and the block makes an indenture or cavity on the inside, corresponding to which there is a prominence on the outside, which stands for part of the figure; and thus the workman proceeds to chase and finish all the parts by the successive application of the block and hammer to the several parts of the design. It is wonderful with what beauty and justness artists, by means of this simple piece of mechanism, represent foliages, grotesques, animals, histories, and the like.

ENCLITICA, in *Grammar*, particles which are so closely united with other words as to seem part of them, as the *que* in *virumque*, &c. There are three enclitic particles in Latin, viz. *que, ne, ve.*

ENCRATITES, in *Ecclesiastical History*, heretics who appeared towards the end of the second century. They were called *Encratites*, or *Continentes*, because they gloried in abstaining from marriage, and the use of wine and animal food.

ENCYCLOPÆDIA, a term nearly synonymous with CYCLOPÆDIA, but adopted in preference to it in denominating the present work, as being more definite and of better authority. According to the observation of that learned printer Mr Bowyer, the preposition EN makes the meaning of the word more precise. For *Cyclopædia* may denote "the instruction OF a circle," as *Cyropædia* is "the instruction OF Cyrus," whereas in *Encyclopædia*, the preposition determines the word to be from the dative of *cyclus*, "instruction IN a circle." And Vossius, in his book *De Vitiis Sermonis*, has observed, "that *Cyclopædia* is used by some authors, but *Encyclopædia* by the best." Some account of the history and merits of the different Encyclopædias which have appeared will be found in the General Preface to this work.

ENDEMIC or ENDEMICAL DISEASES are those to which the inhabitants of particular countries are subject more than others, on account of the air, water, situation, and manner of living.

ENDIAN, a town of Persia, in the province of Kuzistan, occupying both banks of the river Tab, which is here 240 feet broad. It is surrounded by numerous walls, nowhere more than three feet thick, and is nearly two miles in circuit. It contains from 4000 to 5000 inhabitants, and carries on trade with Bassora and with the countries to the east. Lat. 30. 18. N

ENDLESS, something without an end; thus authors mention endless rolls, the endless screw, and the like.

ENDOR, in *Ancient Geography*, a town of Galilee, four miles to the south of Mount Tabor, in the tribe of Manasseh, where the Pythoness was consulted by Saul.

ENDORSED, in *Heraldry*, an ordinary, containing the eighth part of a pale, which Leigh says is only used when a pale is between two of them.

Endorsed, in *Heraldry*, is said of things borne back to back, more usually called *Adossé*.

ENDORSEMENT, in *Law* and *Commerce*. See Indorsement.

ENDOWMENT, in *Law*, denotes the settling a dower on a woman; though sometimes it is used figuratively, for settling a provision upon a parson on the building of a church; or the severing of a sufficient portion of tithes for a vicar, when the benefice is appropriated.

ENDRACHT'S Land, or Concord, is an extensive, low, and sterile tract on the west coast of New Holland, in which is a spacious bay, lately called by the name of the English navigator Dampier, and which was formerly denominated Shark's Bay.

ENDRIE, a town of Asiatic Russia, in the district of Eastern Caucasus. It is situated on the river Akatsch, after it has left the mountains and spread into the plain, nearly about twenty miles from the Caspian Sea. It contains several mosques, an Arminian church, and two synagogues; and is the joint property of several Russian princes, who acknowledge the Russian authority. The inhabitants are chiefly Mahommedans, who allow the most complete toleration to the Georgian and Arminian Christians, and also to the Jews. The latter carry on an extensive commerce. The surrounding country is inhabited by savage tribes, who make frequent inroads on the peaceable inhabitants, and carry off slaves, whom they plunder and sell to the highest bidder, or keep till they are ransomed. Endrie is the seat of this extensive traffic, and is acknowledged as a free town by all the natives of the Caucasus; and it is a great commercial resort. It was formerly called Baal or Balek, and afterwards Endrie, from a governor by whom it was bravely defended against the Arabs. In 1722 it was sacked by the Russians.

ENDYMION, in fabulous history, a shepherd, son of Æthlius and Calyce. It is said that he required of Jupiter to grant to him the privilege of being always young, and sleeping as much as he chose; whence came the proverb of *Endymionis somnum dormire*, to express a long sleep. Diana observed him naked as he slept on Mount Latmos, and was so struck with his beauty that she came down from heaven every night in order to enjoy his company. Endymion married Chromia, daughter of Itonus, by whom he had three sons, Pæon, Epeus, and Æolus, and a daughter called *Eurydice*. The fable of Endymion's amours with Diana, or the moon, arose from his knowledge of astronomy; and as he passed the night on some high mountain in order to observe the heavenly bodies, it came to be reported that he was courted by the moon. Some suppose that there were two persons of this name; the son of a king of Elis, and the shepherd or astronomer of Caria. The people of Heraclea maintained that Endymion died on Mount Latmos; and the Eleans pretended to show his tomb at Olympia in Peloponnesus.

ENEMY, in *Law*, an alien or foreigner, who publicly invades the kingdom.

ENERGUMENS, in *Ecclesiastical History*, persons supposed to be possessed by the devil, and concerning whom there were many regulations among the primitive Christians. They were denied baptism and the eucharist; at least this was the practice of some churches: and though they were under the care of exorcists, yet it was thought a becoming act of charity to let them have the public prayers of the church, at which they were permitted to be present.

ENERGY, a term of Greek origin, signifying the power, virtue, or efficacy of a thing. It is also used figuratively, to denote emphasis of speech.

ENERVATING, the act of destroying the force, use, or office, of the nerves, either by incision, by weakening them with debauchery, or by some other violence.

ENESEI, or Yenesei, a river of Siberia. It has its rise in the mountains of Central Asia, which border on Chinese Tartary, and, taking a northern direction, flows into the Frozen Ocean, after a long course through the plains of Siberia, in long. 82. 14. E. lat. 72. 20. N.

ENESEISK, or Yeneseisk, a town of Siberia, in the government of Tobolsk, situated on the right bank of the river Yenesei. It is of considerable size, is fortified, and has a jurisdiction over an extensive tract, from which a tribute of furs is paid to government. It has several manufactories, of which the most remarkable are those for working up the sea-horn and mammoth teeth into various beautiful articles. It is one of the most antique places in Siberia, the old Russian style of building being still kept up, in which the roofs of the houses project twelve and fifteen feet beyond the walls. In one of the churches here there is a massive candelabrum suspended from the centre. Its weight is a thousand pounds, and its value above L.5000. Long. 91. 50. E. Lat. 58. 16. N.

ENFANS Perdus, the same with forlorn hope.

ENFIELD, William, LL.D. an elegant and justly admired writer, was born in the year 1741, at Sudbury. His original destination was for the sacred office of the ministry, and he was educated amongst the Protestant dissenters at Daventry, where the high polish which he gave to his compositions distinguished him from many of his contemporaries. The congregation of Benn's Garden of Liverpool made choice of him for their minister in the year 1763, when he was not more than twenty-two years of age; and in this situation he was soon taken notice of as an amiable member of society, and an engaging preacher. Whilst he resided in Liverpool, he published two volumes of sermons, duodecimo, as well as a collection of hymns and family prayers, which met with a very favourable reception. In the year 1770 he was appointed tutor and lecturer in the belles-lettres at Warrington academy, which he filled for some years with general approbation and unwearied diligence. He was the compiler of many useful books, amongst the most popular of which we may rank his *Speaker*, consisting of pieces for recitation selected from the best and most approved English authors. At the beginning of this collection there is an excellent essay on elocution. The *Preacher's Directory*, the *English Preacher*, a collection of sermons in 9 vols. 12mo, from the most celebrated authors, and Biographical Sermons on the principal characters in the Old and New Testament, with a number of single sermons on particular occasions, were also the productions of his pen. The controversy relative to literary property likewise engaged his attention, and on this he wrote a quarto pamphlet. He also published, in one volume quarto, *Institutes of Natural Philosophy*, theoretical and experimental; and during the time of his residence at Warrington, as teacher in the academy, the university of Edinburgh conferred upon him the degree of LL.D. When that academy was dissolved in 1783, Dr Enfield continued for two years at Warrington in the capacity of private tutor, after which he was chosen pastor of the Octagon meeting-house at Norwich, in the year 1785. He at length gave up his private tuition, and entirely devoted his time to literary labours, and the peculiar duties of his pastoral charge. About this time he lost his eldest son, who had been appointed to the office of town-clerk of Nottingham. This event would have been productive of very serious effects on his health and spirits, had it not been for the consolations of religion and philosophy, which are sufficient to support the human mind under the pressure of the severest calamities. He undertook and executed the laborious task of abridging Brucker's *History of Philosophy*, which, in 1791, he published in 2 vols. 4to. It has been generally acknowledged that the tenets of the different sects of philosophers were never before exhibited to the world with such perspicuity and elegance; qualifications for which Dr Enfield was undoubtedly eminent. He contributed largely to the Biographical Dictionary published under the inspection of Dr Aiken and others.

An unsuspected distemper hastened the termination of his useful life, and, on the 3d of November 1797, he expired in the fifty-seventh year of his age. That general love of mankind which Dr Enfield possessed, falls to the lot of but few; nor does it often happen that an individual dies so universally lamented. It was essential to him to be amiable in every station and condition of life. His posthumous sermons, in 3 vols. 8vo, had a very numerous list of subscribers; a strong proof of the estimation in which he was held by all who knew him, either personally or by report. In these discourses he treats chiefly on moral topics, which he discusses with the nicest discrimination, and in a train of the most pleasing and manly eloquence.

Enfield, a village of the hundred of Edmonton, in the county of Middlesex, nine miles from London. There are the remains of an ancient royal palace, in which Edward VI. kept his court, and where Elizabeth rested on her way to London in order to assume the crown. Near to it was Enfield chase, disforested in 1779, divided between several parishes and the crown, and now occupied by several country seats of the more opulent traders of London. The parish is extensive, and its population amounted in 1801 to 5881, in 1811 to 6884, in 1821 to 8227, and in 1831 to 8812.

ENFILADE, in the art of war, is used in speaking of trenches, or other places, which may be scoured by the enemy's shot along their whole length. In conducting the approaches at a siege, care must be taken that the trenches be not enfiladed from any work of the place.

ENFINE', formerly Antinoe, a city of Egypt, built by Adrian in honour of his favourite Antinous. It is situated towards the middle of the Saïd, or Upper Egypt, and still contains several stately monuments of antiquity. In ancient times this city was very magnificent. See article Egypt.

ENFRANCHISEMENT, in *Law*, the incorporating of a person into any society or body politic.

ENGANO, or Pugniatan, an island in the Eastern Seas, lying off the south-west coast of Sumatra, being about thirty miles in circumference, and nearly eighteen miles in length. It is covered with trees, and has always a verdant appearance. The natives are taller and fairer than the Malays; the men have black hair, which they cut very short, while it is worn long by the women, and neatly turned up; and they are extremely savage in their manners, the men going entirely naked, and the women having no other covering than a slip of plantain leaf round the waist. Their houses are of a conical form, resembling bee-hives, supported on posts, and standing singly amidst their plantations; and their canoes are formed of two planks sewed together, pointed at each end, and provided with outriggers. An attempt was made by the Dutch in 1645 to commence an intercourse with these people; but it ended in a shameful act of treachery, by which they trepanned about sixty or seventy of the natives, many of whom died after arriving at Batavia. In 1771 another attempt was made by the English settled in Sumatra to gain some acquaintance of the people, but it failed. Long. 102. 20. E. Lat. 10. 20. S.

ENGASTRIMYTHI, in Pagan theology, the Pythias or priestess of Apollo, who delivered oracles internally, without any action of the mouth or lips. The ancient philosphers, and others, are divided upon the subject of the engastrimythi. Hippocrates mentions this peculiar manifestation as a disease; others will have it a kind of divination; others again attribute it to the operation or possession of an evil spirit; and others to art and mechanism. Scottus maintains that the engastrimythi were poets, who, when the priests could not speak, supplied the defect by explaining in verse what Apollo dictated in the cavity of the sacred tripod.

ENGEN, a bailiwick in the circle of the Lake of the Duchy of Baden, in Germany, containing one market town, with eighteen hamlets and 9500 inhabitants, the capital of which is situated on the river Aach, is of the same name, and contains 211 houses and 1204 inhabitants.

ENGENDERING, a term sometimes used for the act of producing or forming any thing. Thus meteors are said to be engendered in the middle region of the atmosphere, and worms in the belly.

ENGHIEN, a city of the circle of Mons, in the province of Hennegau, in Flanders, with 3054 inhabitants, employed in making lace, lace thread, and fine linen. Long. 3. 55. E. Lat. 50. 40. N.

ENGINE, in *Mechanics*, is a compound machine, including one or more mechanical powers, as levers, pulleys, screws, and the like, made in order to raise, cast, or sustain any weight, or produce any effect which could not be easily effected otherwise. The word is formed, through the medium of the French, from the Latin *ingenium*, by reason of the ingenuity required in the contrivance of engines to augment the effect of moving powers.

ENGINEER, taken generally, is a term applied to those who are employed in devising or forming engines or machines, and in directing their applications. In a more restricted and appropriate sense, it denotes two very important professions; the one that of the *military*, the other that of the *civil* engineer.

The *Military Engineer* is an officer whose business it is to delineate the plans and direct the formation of military works, and to regulate attacks and defences. Those branches of knowledge which more particularly relate to his profession are treated, in this work, under the heads of Artillery, Fortification, Gunnery, and War.

The *Civil Engineer* is a person who applies the principles of mechanical and physical philosophy to the construction of the machines and public works by which the arts and accommodations of civil life are rendered more efficient, extensive, and secure. The subjects which more immediately belong to his important calling are treated in this work under the heads of Bridge, Carpentry, Docks, Gas Lights, Harbours, Light-houses, Navigation, Navigation Inland, Railways, Roads, Tunnels, Water-works, &c.; and also under the heads Dynamics, Hydrodynamics, Machinery, Mensuration, Resistance of Solids, Strength of Materials, &c.

ENGLAND,

The southern division of the island of Great Britain. In treating of this grand division of the British empire, we shall divide the subject into three Parts; the first comprehending the History of England, the second the Statistics of that country, and the third some account of its Government and Laws.

PART I.

HISTORY.

The history of England, till the period of the Saxon Conquest, has been fully treated of in the first chapter of the article Britain. After that event the country relapsed into a state of obscure barbarism, nearly as great as that from which it had been rescued by the Romans. The provincial Britons had profited by their intercourse with that great people. From the latter they had learned many of the arts of civilized life, and during the period of their subjugation they had erected a considerable number of cities, towns, and villages; but these were subsequently levelled with the ground by barbarian invaders, and the natives were frequently involved in the same ruin with their habitations. We are informed by one historian that a mighty conflagration began on the western coast, and gradually extended itself over the whole island. To escape from the exterminating swords of the Saxons, the Britons sought refuge in their native fastnesses; and thus the spark of civilization which had been struck out amongst them, and which, in more auspicious circumstances, might have kindled into a generous flame, was totally extinguished.

About the year 700, the island of Great Britain was divided into no fewer than fifteen sovereignties. Of these, eight were Saxon; but the union of the two Northumbrian principalities reduced the number to seven; and from this circumstance, as well as from some vague alliance amongst these petty states, historians have designated the whole by the name of the Heptarchy. They ruled over a considerable portion of England, and whilst they waged a fierce and endless war with every other kingdom in the island, they also maintained amongst themselves a continual struggle for the superiority. It would appear that one state usually exercised an undefined power over all the others; and the prince who possessed this equivocal ascendency had the title of *Bretwalda*, or wielder of the Britons, bestowed upon him. The history of this period is not characterized by any event which would lead us to take an interest in the fluctuating fortunes of the various states. Our information relating to the earliest portion of the Saxon rule is also scanty; but what we do possess is not of such a nature as to awaken any feelings of regret that more minute particulars have not been transmitted to us. Details of the shedding of kindred blood, and acts of oppression, treachery, and cruelty, exercised towards the natives by the fierce invaders of their soil, are not calculated to interest human feelings. The re-introduction of Christianity, however, in some degree alleviated the darkness of the picture. The exact date of its first appearance in Britain is uncertain, but it had made some progress before the close of the second century. It disappeared however, with the other traces of civilization, when the Saxons commenced their devastations. It was in the year 596 that Gregory the Great sent over St Augustin, with forty other missionaries, to convert the Saxons; and their arrival in Kent marks a new era in its history, and probably in that of the country. At this period Kent was governed by Ethebert, an able and powerful monarch, and the third who bore the title of Bretwalda. He received kindly the deputies of Rome, and became a convert to their doctrine; an example which his subjects were not slow in following. From this period the spread of the Christian faith over the island appears to have been rapid; for we find that in about a century after the arrival of St Augustin it was professed and believed throughout Anglo-Saxon Britain. That it conferred many temporal benefits upon the community, cannot be doubted. But, however its divine precepts may have influenced the conduct and ameliorated the lot of individuals, crimes upon a great scale continued to be perpetrated as formerly. It may have mitigated the horrors of war, but battle followed on battle with as uniform a succession, and native blood flowed as freely, as heretofore. The continual struggle amongst the Anglo-Saxon principalities for the supremacy was however fast coming to a crisis. It is evident that such a state of affairs could not continue for any length of time, and that it must necessarily end in the establishment of a regular hereditary magistracy in the island. This took place partially at the beginning of the eighth century, in the person of Egbert, king of Wessex, who was a lineal descendant, and the only surviving prince, of the house of Cerdic, the founder of that kingdom. The great talents which he early exhibited had given offence to Brihtric, king of Wessex, who, jealous of his popularity, projected his destruction. Egbert, however, eluded his vengeance, and fled for protection to Offa, king of Mercia, a monarch illustrious for the talents he displayed and the prosperity he enjoyed, but whose name is stained with perfidy and blood. Thither the vindictive Brihtric pursued the youthful fugitive, who was finally compelled to cross the channel and to seek shelter beneath the broad shield of the victorious Charlemagne. France, governed by that renowned sovereign, excelled all the states of the West in civilization and the arts of government, as well as those of war. Trained in such a school, therefore, and early disciplined by adversity, he was undergoing an admirable probation for wielding with judgment and moderation the perilous sceptre which was destined to be transferred into his hands. The death of Brihtric, who perished by the machinations of his queen, recalled the fugitive from his exile. In Wessex the claim of Egbert was at once acknowledged, while his accession to the throne of his celebrated ancestor, an event highly popular in itself, was ennobled by a victory, the omen of many a future triumph.

A. D. 800. At this period the island, though nominally under a hexarchy, was rapidly verging to a triarchy, from several of the smaller states becoming gradually blended and identified with their more powerful neighbours. Wessex had been enlarged by the incorporation of Sussex; and various favourable circumstances conspired to concentrate in the hands of Egbert a well-organized power, which he was prepared to wield when summoned by any great emergency. For several years, however, after his accession to the throne, his sword remained in its sheath; and this propitious period of tranquillity afforded him an opportunity of turning his undivided attention to the affairs of government. His administration was as mild as it appears to have been politic; circumstances which completed the attachment of his subjects, and consolidated his growing strength. It was upon the unfortunate Britons of the west that he first made trial of his military prowess. About the year 809 the struggle between him and the natives commenced. The latter made a strenuous but unavailing resistance; and Egbert carried the havoc of war and the flames of destruction from the east to the west. In a few years the greater part of modern Wales, as well as the people who occupied the northern shore of the estuary of the Severn, acknowledged his authority. The king of Mercia, whose strength had been augmented by the appropriation of the petty sovereignties of Kent, Essex, and East Anglia, was now the only rival for the supreme authority whom Egbert had to fear or to contend withal. Their power was nearly equally balanced, for what Wessex wanted in numerical force was compensated by discipline and skill. War had now become inevitable; neither would brook a superior, and only one Bretwalda could be acknowledged. The conflict began, therefore, and was speedily brought to a termination. In an obstinate and bloody battle the king of Mercia was totally defeated, and Egbert became lord of the ascendant. State after state was annexed to Wessex; Mercia was invaded and subdued; and in nineteen years after he had first drawn the sword, Egbert was acknowledged over the greater part of the island as the eighth Bretwalda.

The authority of Egbert, however, still continued doubtful; and the Anglo-Saxon power was as yet very far from being consolidated. The fortunes and immunities of those composing the several states were not dependent upon one common legislature; and in regard to the details of government, the whole principalities remained as distinct from each other as before. Wales still continued to annoy him; and it was not until he had marched an army to Snowden that North Wales quietly submitted to that of the Saxon Bretwalda. But new and more formidable enemies than any he had yet encountered had begun to threaten England, and trouble the tranquillity which it in some measure enjoyed. These were Scandinavians, recognised in France by the name of Normans, and in England by that of Danes. Familiarized, from their maritime situation, to the dangers of the ocean, this people, like the Saxons of old, spent the greater portion of their time upon its waves. A pernicious law of succession, which consigned the whole patrimony to the eldest son, drove the younger branches of families to seek their fortunes by means of their ships and their swords. It was only in this manner that they could acquire riches and renown; and such pursuits were peculiarly agreeable to a people who unhappily preferred the acquisitions of rapine to the fruits of laborious industry. It was the custom of these pirates to set sail for some distant province in squadrons, under the command of chieftains called *Vikingr*, or Sea-Kings. After pillaging the coast where they landed, they collected the spoil and returned to their own country, where they disencumbered themselves of their booty and prepared for fresh expeditions. Three descents upon England are recorded as having taken place in the eighth century, but these attempts produced no permanent alarm. Towards the termination of Egbert's reign, however, the numbers of the pirates greatly increased, whilst their visits were annually renewed; and for two centuries to come the country was destined to be a prey to these fierce and fearless invaders.

After making several successful inroads into various parts of England, in 835 they landed on the coast of Cornwall, where they succeeded in seducing the Britons from their allegiance. The king of Wessex met the united forces of the enemy at Hengstone Hill, and gained a bloody but decisive victory, which restored the glory of his arms. This was the last exploit of Egbert, who died the year following, after a reign as prosperous as it was long, and which, allowing something for the condition of society at the period, may also be termed glorious.

Ethelwolf succeeded his father on the throne of Wessex; but an unfortunate arrangement, by which the former king bequeathed all his dominions except Wessex to a younger son, greatly weakened the power of his successor, and lessened the influence of the Bretwalda. Ethelwolf had been a monk, and appears to have been better adapted for the cloister which he had left than the throne which he now ascended. The history of his reign presents little of interest or variety. It is merely an account of the atrocities of the Danes, who made repeated descents upon England, laying waste the country, plundering towns, and despoiling the rich monasteries, where treasure was supposed to have been accumulated. No defeat, however signal and decisive for the time, was capable of permanently expelling them from the island; and although routed and compelled to flee for shelter to their ships one year, they returned the next with persevering audacity. In the meanwhile Ethelwolf found leisure to perform a pilgrimage to Rome; and in passing through France on his journey homewards, he espoused Judith the daughter of Charles the Bald, king of the Franks. But he was not permitted to enjoy undisturbed domestic tranquillity. On his return to England he found his son Ethelbald at the head of a formidable conspiracy, which threatened him with deposition and exile. The two parties, however, came without bloodshed to terms of accommodation. It was agreed that Ethelwolf should possess the eastern states appertaining to Wessex, whilst the kingdom of Wessex proper, which belonged of right to the head of the family, should be enjoyed by Ethelbald, but, it would appear, with a nominal subjection to his father. Ethelwolf survived these arrangements only a few years, having died in 858.

After his demise Ethelbald continued to occupy the throne of Wessex; whilst Ethelbert, a younger brother, succeeded to the government which had been left vacant by the death of his father; but both these princes died in a few years, and left their thrones to their brother Ethelred, who assumed the sceptre at a most unpropitious period. Not only was the kingdom divided against itself, but the Danes, acting now in a well-organized confederacy, and terrible from their numbers as well as from the frequency of their inroads, threatened the total annihilation of the Saxon dynasty and the subjugation of the island. In the reign of Ethelred ancient chroniclers present us with little else than accounts of battles fought and towns sacked, prolonged by all the sickening minutiæ of rapine and bloodshed. The conflicts were numerous and sanguinary; and in one of these, which took place at Merton in the year 870, the king received a wound of which he soon afterwards died.

By the death of Ethelred the throne of Wessex devolved upon Alfred, the fifth and favourite son of Ethelwolf. As an account of this extraordinary individual has already been given under the head of Alfred, it is unnecessary to recapitulate the events of his life. He was succeeded by his son Edward, who ascended what may now almost be termed the throne of England, in the year 901. Alfred had been called to the crown in preference to the children of his elder brother, who were considered at the time as too young to be entrusted with the government. Their pretensions being also set aside at his death, Ethelwold, one of the rejected princes, attempted by violence to seize hold of the royal authority. He formed an alliance with the Danes and other enemies of Edward; but in a battle with the men of Kent he met his fate, and the island was once more rescued from a destructive competition for the crown.

Previously to this event the Danes had contrived, by a union with some of the disaffected provinces, to obtain a kind of permanent footing in the country. They possessed the north of England from the Humber to the Tweed, and the eastern districts from the Ouse to the sea. Emboldened by their strength, they invaded Mercia, but were met by Edward, who obtained over them a decisive victory, which effectually restored his supremacy. The most remarkable individual after Edward was his sister Ethelfleda, upon whom the mantle of Alfred seems to have descended. She governed Mercia, and vigorously seconded her brother in fortifying the country against the common enemy. Upon her death in 920 the Anglo-Saxon monarchy received additional security from the final incorporation of Mercia with Wessex. After various successes over his northern and other enemies, Edward the elder expired at Farrington in Berkshire, in the year 924. This monarch would appear to greater advantage were he not viewed in such close proximity to Alfred the Great, the brilliancy of whose reign was calculated to eclipse that of his successor, had the latter been even a greater man than he actually was. Edward, however, was a great man, and every way worthy to wield the sceptre of his father, which he did with uncommon judgment and success.

He was succeeded by his son Athelstane, whom historians, on the faith of an old song, are in the habit of styling illegitimate; but a contemporary poetess has recognised his mother as the partner of Edward's throne, a circumstance which fairly balances the former authority. There is one argument in favour of his legitimacy, which, as far as we are aware, has been overlooked; it is the exceeding partiality evinced towards him by his grandfather Alfred. It seems improbable that an individual, whose moral rectitude and ardent piety were so conspicuous as those of Alfred, should have singled out as his especial favourite one whose birth was a public scandal; that he should also have invested him with the insignia of knighthood whilst yet a child, and looked upon him as the future hope of Britain, more especially as, supposing the youth to have been a natural son, the legitimate children of his father had a preferable right to the throne. Viewing the matter in this light, the truth of the hypothesis that Athelstane was the fruit of a union sanctioned by law and religion appears highly probable, even allowing that the distinction of natural from legitimate children was at that period somewhat faint. It does not appear to have been so in the mind of Alfred the Great.

Athelstane was thirty years of age when his father expired; and Mercia immediately, and Wessex shortly afterwards, recognised him as king. Opposition was, however, experienced in other quarters; but he ultimately succeeded in seating himself firmly upon the throne, and fully justified the early popularity he enjoyed with his grandfather. In the person of Athelstane the Anglo-Saxon sovereign became a character of dignity and consequence in Europe. His connections with the most respectable potentates on the Continent gave to his reign a political importance, and he is moreover entitled to be considered as the first monarch of England.

The sovereignty of the whole island appears to have been the object of Athelstane's ambition. In his military enterprises he was completely successful, and compelled the princes of the Scots, Cambrians, and Britons, to swear fealty to him, in the same manner as the Saxon vassal was accustomed to swear to his lord. But his prosperity was interrupted by a powerful confederacy formed against him, which threatened not only to emancipate Northumbria from his authority, but even to overwhelm his hereditary government. The confederates were Constantine king of the Scots, and Anlaff the son of Sigtryg or Sihtric, who was king of Northumbria at the time of Athelstane's accession. Anlaff had received the hand of Athelstane's sister; but he drove her from his court, for which barbarous conduct the Anglo-Saxon monarch stripped him of his kingdom and ejected him from the island. Anlaff had fled to Ireland, whence he returned with a large fleet, in order to retaliate the insult of his expulsion. The remaining malcontents were the Welsh princes who had been humbled into submission, the Danes who inhabited the eastern coast from Tweed to Thames, the petty states of Cambria, and a constantly increasing host of lawless pirates and freebooters from Scandinavia.

A.D. 937. Athelstane prepared with firmness and energy to meet the storm which threatened him with destruction. The armies met at Brunanburgh in Northumbria, and a battle was fought, celebrated in Saxon and Scandinavian poetry. The confederates were routed with great slaughter, and Anlaff and Constantine effected their escape with great difficulty. So complete was the overthrow, and so decisive the victory, that the remainder of Athelstane's reign was undisturbed by the rebellion of his subjects or the invasion of a foreign enemy. The throne of his ancestors was now effectually secured to him; and the Britons were so completely humbled, that to him belongs the glory of having been the founder of the English monarchy. The fame of his accomplishments, his talents, and his successes, was not confined to the insulated kingdom which he governed; it extended throughout all Christendom. With several foreign courts he maintained a friendly correspondence; and three princes, who afterwards became eminent in Europe, were fostered under his care, and restored by his aid or influence. These were Haco of Norway, Alan of Bretagne, and the son of his sister, Louis d'Outremer, so called from his residence in England. A concern in the death of a brother named Edwin is generally ascribed to him, but the story is somewhat doubtful; and if the other events of Athelstane's life, his public services and private virtues, be allowed to have any influence upon our judgment, it must be pronounced as improbable. Athelstane died in the year 940, regretted by his subjects, amongst whom he was revered as a prince alike distinguished for wisdom, justice, and benevolence.

Having left no issue, he was succeeded by his brother Edmund, who perished by the dagger of an assassin six years afterwards. The life of this king is not characterized by any events of importance. He was succeeded by his brother Edred, whose reign was short, and distinguished by no remarkable circumstance, except the complete incorporation of Northumbria with the rest of the Anglo-Saxon kingdom.

Edred died in 955, and left the throne to Edwin, who is usually styled Edwy, the eldest son of Edmund the Elder. The name of this monarch is intimately connected with that of the celebrated Dunstan, abbot of Glastonbury. The life of that individual having been already given under the head of DUNSTAN, we shall only mention here a few circumstances which are indispensably necessary to the complete chain of historical events. The reign of his uncle Edred had been looked upon by Edwy as a usurpation, and when he himself ascended the throne, the counsellors of the former monarch became the objects of his antipathy. He discarded them altogether, and surrounded himself with a host of young courtiers, more ready to emulate the vices of their master than to suggest prudent measures of government. At their instigation Edwy imposed unjust taxes upon his subjects, despoiled the clergy, and committed other unseemly acts. Dunstan, having been one of the leading advisers of Edred, was most probably obnoxious to the young king; and at his coronation a circumstance occurred which brought the hostile parties immediately into collision. On that day Edwin, after the ceremony, withdrew from the festive board at which the nobles and clergy were regaling themselves, and retired to his own apartments. This indecorous act appears to have displeased the assembly; and Odo, archbishop of Canterbury, deputed Dunstan and another individual to bring back the king to join in their carousals. Dunstan penetrated into the private apartments of his sovereign, whom he found in company with Ethelgiva or Elgiva, his wife or mistress; the mother of the latter was also present. The two deputies forcibly tore the king from the company of the ladies, and brought him back to that of the nobles. This daring and insolent conduct of the monk towards the newly-consecrated monarch drew down upon him the royal vengeance. At the instigation of Elgiva, Dunstan was deprived of his honours, and condemned to exile. During his absence, Odo contrived to take Elgiva from her husband's residence, and send her a prisoner to Ireland, where her face was branded with red-hot irons, for the purpose of obliterating her charms; but in vain. They revived with the healing of the wounds; but on her return to England she was pursued by the opposite party, who falling in with her at Gloucester, actually hamstrung the unfortunate fair one. In a few days death released her from the vengeance of her enemies and from her own sufferings.[1] In the meanwhile a conspiracy was formed against the now unpopular Edwy; and at the head of it was his brother Edgar, who, supported by the Northumbrians and Mercians, drove the unfortunate monarch beyond the Thames. His sufferings and humiliation, however, were of short duration, for he died in 959, ere he had attained the full age of manhood. By some historians he is said to have been assassinated; others state that he pined to death for the loss of his throne, and his Elgiva, whom he tenderly loved; but all agree that his demise was as miserable as it was premature. His youth was the source of all his calamities, for it seems certain that he was only sixteen or seventeen years of age when he assumed the sceptre. He had also the misfortune to live at a very critical period. It was the commencement of that struggle between seculars and regulars which was to be maintained for many centuries thereafter. The intrusion of Dunstan into the king's private chamber was the earnest of many a bold step upon the part of the clergy. It is thus memorable as being one of the earliest instances in our history, of the putting forth of that overwhelming strength with which the church of Rome was armed, and which was destined ere long to exercise so preponderating an influence over the political affairs of every court in Christendom, whose haughtiest monarchs were soon taught to tremble at the thunder of the Vatican.

The death of Edwin put his brother and rival Edgar in peaceable possession of the whole Anglo-Saxon territory. His reign was tranquil, neither foreign enemy nor domestic broils having interrupted its quiet, so that posterity has styled him "the peaceful." The only event of a warlike character ascribed to him is an invasion of Wales. In his personal character he was distinguished alike for his religious zeal and for his licentiousness. A few facts relating to each of these may be stated here. He espoused the cause of the monks, and, during the sixteen years of his reign, erected a vast number of Benedictine monasteries. He recalled Dunstan from exile, placed the bold saint at his right hand as chief counsellor, and conferred upon him the see of Canterbury. In this situation that celebrated ecclesiastic prosecuted his ambitious schemes connected with the order to which he belonged with redoubled vigour. He expelled the clergy from the monasteries, and supplied their places with Benedictines, making the rule of their founder everywhere predominant throughout the nation.

We now find the church so intimately mixed up with political affairs, that some account of it is necessary for the elucidation of history. Although religious individuals had been collected in monasteries from the period of Augustin's landing in Kent, yet the order of Benedictines seems to be the most ancient example of monastic rule. Each congregation of recluses lived according to its own internal regulations, nor were the several monasteries consolidated into one community before the time of Dunstan. The Scottish or Irish, the Pictish and British churches, though in communion with Rome, were still independent of the papal see; and it was the object of the popes to suppress this independence of the different national churches; a cause which was warmly espoused by Dunstan. His policy was to enforce clerical celibacy; to expel at least all the married clergy from canonries and prebends in cathedrals, in order to make way for Benedictines; and to reduce all monasteries to the rule of the founder of that order. The opposition he encountered was formidable, and the cause of the clergy was espoused by the laity. Amongst the latter the secular priests found many powerful partizans, and the schisms of the church at last degenerated into factions amongst the people. But Dunstan was impetuous, and determined to carry through the reformation which he had begun, for he looked upon himself in the light of a reformer; and although the extension of his own power and that of his order may have been so blended with his zeal for the service of God as to deceive even himself, yet there seems no reason to doubt his sincerity. That there were many clerical abuses to be corrected, is consistent with the history of religion in all ages. The Danish invasions, and other national calamities, dispersed the clergy amongst the laity, with whose vices they doubtless became contaminated. The necessities of his situation compelled the prelate to be a statesman and an intriguer. He made some progress during the reign of Edred; in that of Edwy we have seen him checked; but in the present one, invested with the highest ecclesiastical dignities, and backed by the power of his sovereign, he appears before us under auspices which enabled him to carry his loftiest projects into execution. And he was not slow in seizing the opportunity. Not content with the ordinary engines of intrigue and supple policy, he drew upon the superstitious feelings of the time, and arrogated to himself divine intuition and the power of working miracles. He succeeded in deceiving that unenlightened age, and perhaps also himself.

The foregoing remarks may afford a key to some of the more prominent events of Edgar's reign. A national synod was held, at which the king publicly expressed his sentiments in favour of the Benedictine cause. It followed as a consequence of this, that the unfortunate seculars were ejected if they refused to comply with the enactments made by Dunstan and his party, under the sanction of the sovereign; whilst monks were everywhere received with honour, and the erection of monasteries was for a time a royal mania. During the sixteen years of his reign Edgar built no less than forty-eight of these establishments.

---

[1] There is no direct proof that this atrocity was perpetrated under the sanction of the Archbishop of Canterbury; and it is impossible to implicate Dunstan in the guilt, for he was in Flanders at the time. The deed, however, was done by the adherents, and praised by the encomiasts, of the archbishop.

In the midst of all this holy zeal, however, he found leisure for the indulgence of his licentious appetites. On one occasion he violently carried off a young lady educated in a convent, and made her his concubine. For this offence he was reproved by Dunstan, and compelled to do penance during seven years; but the mortifications imposed were not of a very severe character. His second marriage was connected with circumstances of a very tragical nature. The beauty of a young and noble lady having been praised to him, he commissioned Ethelwold, a favourite minister, to visit her residence, and report upon her charms. The deputy was himself captivated with the lady. He represented her in an unfavourable light to his sovereign, and married her himself; but Edgar, not being satisfied with the report, paid a personal visit to Elfrida, and, fascinated by her beauty, he procured the destruction of her husband, and espoused the bereaved lady himself.[1]

In extenuation of these delinquencies, he has been allowed the honourable distinction of having warmly patronized trade with foreigners. His commuting the tribute from Wales into three hundred wolves' heads, and his reformation of the coinage, also redound to his credit. By his orders a numerous fleet constantly guarded the kingdom from invasion, and he regularly visited his provinces in order to countenance the execution of the laws. His reign was glorious, and he seems to have converted his prosperity into ostentatious pomp. It is stated that eight kings, amongst whom were Kenneth of Scotland, and his son Malcolm of Cimbria, did him homage by rowing his barge down the river Dee.

Edgar died in 975, in the thirty-second year of his age, and was succeeded by Edward, surnamed the Martyr, his eldest son. A younger brother, Ethelred, by Elfrida, disputed the crown with Edward; but the latter was finally established upon the throne through the influence of Dunstan. His reign was chiefly occupied with disputes between the two clerical systems before mentioned, Elfrida having, on account of her son Ethelred, espoused the cause of the seculars, in opposition to Dunstan, who headed the regulars, and who was also the means of supplanting her son. The monks gained a complete victory over the seculars, who were now totally expelled from their convents. During this reign occurred that tragical circumstance which has afforded modern historians an opportunity of accusing the primate of murder. A council of nobles had been summoned to meet at Calne. During the proceedings, and just as the wily Dunstan had pronounced these words, "I confess I am unwilling to be overcome; I commit the cause of the church to the decision of God," the floor fell instantly down, and numbers of his opponents were killed and wounded. The primate, and probably his partizans, escaped unhurt, a circumstance which can only be accounted for by supposing that their seat remained unmoved. Some historians charge Dunstan with having secretly loosened the floor from the walls, and affirm that during the debate the temporary props which supported it were withdrawn according to his directions. This is very improbable; but there can be little doubt that he interpreted the occurrence as a divine judgment upon his enemies, and thus wrought upon the prejudices of that superstitious age. Several heinous crimes are laid to the charge of the queen dowager, but the last was the darkest and most atrocious of all. Edward, in one of his hunting excursions, visited Corfe Castle, in Dorsetshire, where Elfrida resided with her son Ethelred. He was received with the utmost cordiality, and invited to enter the castle, but declined, requesting at the same time to see his brother, and also the favour of some refreshment. Whilst in the act of raising a cup of wine to his lips, he was mortally stabbed in the back by the orders of his stepmother. On account of his violent death he has been surnamed the Martyr.

Edward was succeeded in 978 by Ethelred, the unconscious cause of his untimely fate. When the latter attained the crown he was only in his boyhood, and throughout a long life he never rose above it. This is one of those reigns which it is painful to narrate. It was the saddest which the descendants of Alfred yet had seen, and presents a strong contrast to that of his father. Edward compelled kings to be his watermen. His son by Elfrida became the sport of traitors; and having five times purchased his crown from the roving Danes, he was forced at last to make an ignominious surrender of it to a foreign invader.

For more than a century the Northmen had formed the chief part of the population of Northumberland and East Anglia, and they now stretched their power to the utmost in order to place one of their chiefs upon the Saxon throne. In 980, and for ten years thereafter, England was insulted by a series of inroads, which, although unimportant of themselves, were calculated to excite some alarm amongst the people, when the latter contemplated on the one hand the power and audacity of the Danes, and on the other a pusillanimous monarch and an unguarded country. But these petty aggressions were followed, in 991, by the appearance of a formidable armament upon the English coast. The invaders advanced without opposition as far as Malden, where they gained a victory, and their retreat was disgracefully purchased by a bribe of ten thousand pounds. Repeatedly afterwards did the Northmen play the same game, and Ethelred make the same debasing submission, by purchasing a momentary respite from their ravages. But the very means which were employed to rid the kingdom of these invaders one year, insured their return the next. Treason, famine, and disease, also aggravated the calamities which overwhelmed the nation. Amongst the instances of defection, that of Alfric, earl of Mercia, demands particular attention. On account of his misconduct he had been deprived of his government, but had recovered it again through the influence of his friends. In 992, a meeting of the witenagemote took place at London, where it was resolved to put the kingdom in a posture of defence, by constructing a powerful fleet, and manning it with picked men. This was accordingly done, and the command of it conferred upon Alfric, with another nobleman and two prelates. Their commission was to surprise the Danes at some part where they could be surrounded; but this judicious scheme was foiled by the treachery of the commander, who not only gave the Danes notice of the intentions of the English, but consummated his perfidy by secretly joining them. He urged an immediate flight; but in the pursuit his vessel was taken, though the traitor himself escaped. The king revenged himself upon Alfric, by ordering his son Algar to be deprived of his eyes; an act as barbarous as it was useless.

---

[1] Dr Lingard, in his *History of England*, vol. i. p. 333, states that he is disposed to doubt this tale as improbable. "Malmesbury," says the learned and able historian, "on the faith of an ancient ballad, has transmitted to us a story probably invented by his (the king's) enemies." The story *may* possibly have been invented by his enemies, but where is the evidence, direct or indirect, that this was the case? Dr Lingard goes on to say, "it is improbable in itself, and supported by questionable evidence." Now, where lies the improbability? The tragical character of the transaction is in perfect keeping with that of the times in which it was committed; and as for the perpetrator himself, does not the abuse of the nun prove that, in order to gratify his unhallowed desires, even the religion, for the propagation of which he displayed such unbounded zeal, offered no impediment. Was the law of nature with regard to moral evil stronger in his mind than that which religion had imposed? This is much to be doubted. Nay, it may be surmised that the erection of so many monasteries was a voluntary penance which his conscience dictated him to perform, in extenuation of such crimes as those that are laid to his charge. The evidence is also said to be questionable; but if historians, and the learned Doctor along with the rest, unhesitatingly embody as historical facts the events and transactions related in similar compositions, we see no reason for making an exception with respect to the legend before us, because it happens to stand in the way of a favourite hypothesis. If we take one we must take all, exceptions being made where there is direct contradiction by more authentic evidence, which is not the case in the present instance. Sir James Mackintosh observes, "William of Malmesbury, who might have known the counsellors of Edward the Confessor, relates the incident on the authority (not to be despised) of a Saxon song. The same story is told by a later chronicler called Brompton (*Dec. Scrip.* 865), at great length, and with particulars characteristic of barbaric manners."

This bold exertion on the part of the invaded compelled the Danes to transfer their arms from the south to the north of England, where they extended their ravages; but in 994 appeared two new and more powerful chieftains, Sweyn, king of Denmark, and Olave, king of Norway. With ninety-four ships they sailed up the Thames, and, although repulsed at London, they succeeded in ravaging several counties. But another humiliating subsidy redeemed England from their grasp; and, what is more astonishing still, Olave was honourably received at the court of Ethelred, where he pledged his word never to molest England more. This promise is only remarkable inasmuch as it was faithfully kept. The army of his companion Sweyn, however, continued to occupy the country, to which in course of time it became almost naturalized. That it should remain inactive was not to be expected; but that with impunity it should have been allowed to despoil provinces, displays a want of firmness, courage, and national spirit, which seems unnatural to the island, and can only be accounted for by supposing the existence of a weakness almost amounting to imbecility in the sovereign or his counsellors.

In 1002, Ethelred having lost his first wife, who bore him ten children, married a Norman princess, who assumed the name of Elgiva. The same year became memorable in the history of England for the perpetration of a crime of as black a dye as ever darkened the annals of any people. This wicked act, which rose out of a mischievous policy, is known by the name of the Massacre of the Danes. On the 13th of November, the festival of St Bride, the unsuspecting Northmen, with their wives, children, and all belonging to them, were cruelly put to death by a royal warrant. The details of this fearful transaction are too horrible to be related. Suffice it to say, that no place, however sacred, saved the victims from their pursuers; and that when they fled to the churches for shelter, they were slaughtered in crowds around the altars. One painful episode is interwoven with this tale of blood. Gunhilda, the sister of Sweyn, king of Denmark, who was wedded to an English earl, saw her husband and children massacred before her eyes, and was herself afterwards beheaded. It is related by all historians, that in the agonies of death she foretold the vengeance which would descend upon the English nation for the barbarous act which it had committed; and the prediction was realized, as we shall hereafter see.

The calamities of England seemed now to thicken as the atrocities of its ruler grew darker. Common pity for the failings of humanity would lead us to pardon Ethelred's pusillanimity; but this dark deed has affixed a blot to his scutcheon too deep for time ever to wash away. Sweyn was not slow in revenging the fate of his countrymen; and, through negligence and perfidy on the part of England, he succeeded in ravaging the island, for several years. almost with impunity. In 1007, thirty-six thousand pounds of silver abated his thirst of revenge. Two years afterwards the most powerful armament which had yet obeyed the flag of England was collected at Sandwich; but treason again paralyzed its operations. The captains abandoned their vessels, which were steered up the Thames by the mariners. "Thus," say the annalists, "perished all the hopes of England." The surrender of sixteen counties, and forty-eight thousand pounds, stayed for a short period the rapacity of the Northmen. The picture which the now fallen and devoted England presents, it is painful to contemplate. Accumulated treasons and defeats had unnerved the courage of the natives; whilst the numerous victories of the Danes had swelled their pride, and inspired them with a preposterous idea of their warlike powers. Many fortified cities withstood all their assaults; but the open country was abandoned to their rapacity. Systematic destruction and spoliation was their principle; and the fields, deserted by the husbandmen, ceased to yield the necessary supplies of food, so that the Danes themselves were compelled to quit the island in search of provisions. Taxation, direct and annual, which must be traced to this period, weighed also upon the energies of the people, and materially increased the now almost universal discontent. In the midst of this ignominious submission and disaffection, it is pleasing to record instances of magnanimity, and painful to reflect that these were so few in number. The Archbishop of Canterbury having been made a prisoner by the Danes, was offered his liberty for a moderate ransom, on condition that he would advise Ethelred to pay them heavy sums of money as a largess. "I have no money," he replied, "and I will not advise the king to dishonour himself." Still they persisted; but the dauntless prelate remained unshaken. The barbarians condemned him to death; and he was immediately assailed with bones, horns, and other remains of a feast in which they had been indulging. "Gold, bishop; give us gold," they exclaimed, as they dragged him forth; but he remained unmoved, and having been felled to the earth with the rude missiles which were showered upon him, he received a mortal stab from the hand of a man whom he had himself baptized.

Sweyn made his last incursion into the country in 1013. Terrified at the universal disaffection, Ethelred fled at last to Normandy, whence he returned on hearing of Sweyn's death, which occurred shortly afterwards. The latter was succeeded by his son Canute; for the Danes would now appear to have put in a claim for the sovereignty of the whole country. Ethelred was recalled by the English chiefs, who exacted a promise from him that he would govern with less tyranny than formerly; and pledges were also interchanged between the Danes and English. But a contest soon ensued between the two parties; and although Ethelred succeeded in repeating upon a small scale that system of treacherous massacre for which he had so severely suffered, yet Canute maintained his superiority in open warfare, and took a barbarous revenge upon the hostages in his hands, for the murder of his friends. Treason again added a fearful contribution to the accumulated evils which surrounded the unfortunate Ethelred. His son Edmund, surnamed, from his hardihood, Ironside, vainly attempted to make head against the Danes; for Canute penetrated to York, where he was joined by the Earl of Northumbria and a number of the people. The country was now a prey to two contending armies; but just at this crisis it was relieved from its greatest enemy, Ethelred, who died towards the end of 1016, worn out by care and disease.

Edmund Ironside was immediately chosen king by the English; and if the exertions of one man could have saved the country, this achievement would have been performed by the new king. During his short reign, for it extended to only a few months, he gave proofs of bravery and ability equal to any exigency, and worthy of a happier fortune. The first struggle between him and Canute was for the possession of London, which was held by the English. During the siege Edmund fought two battles in the provinces, one of which took place at Searston, and is celebrated by our annalists. Twice the darkness of night came to the relief of the exhausted armies, which had both suffered severely; but the dawn of the third morning showed the result to be in favour of the English. Canute, however, had taken advantage of the night, and marched upon London. Not long afterwards another battle was fought, in which Edrie, a traitor thrice steeped in infamy by his defection, played the game of victory into the hands of Canute. After this calamitous event the greatness of Edmund's soul became more conspicuous. Although a numerous army had again rallied around his standard, he shuddered to lavish more of his country's blood in this murderous warfare, and challenged Canute to decide their quarrel by single combat. Whether this proposal was accepted or not, is matter of uncertainty; but at all events a pacification was shortly afterwards agreed upon, and England was divided between the rivals; the north being given up to Canute, whilst Edmund retained possession of the south. The latter, however, died shortly afterwards; and there is reason to believe that he perished through the machinations of the perfidious Edrie.

Edmund left two sons, infants; but by the unanimous voice of the nation Canute obtained the sovereignty of England. This remarkable prince was only twenty years of age when he assumed the reins of government. His qualities as a monarch were of a very high order, not unalloyed, however, with the ferocity natural to the Northmen of the period. The first object of his policy was the removal of the children of the two preceding kings. Some of the sons of Ethelred were slain, and the rest consigned to banishment; whilst those of Edmund were sent over to Sweden, for the purpose of being dispatched. But their fate was averted by the prince to whom they were conveyed. He sent them both to the king of Hungary, by whom they were educated in a manner befitting their station. One died in his youth, the other married the daughter of Henry, the emperor of Germany; and their issue was Edgar Atheling, who will be mentioned hereafter.

Canute divided the kingdom into four governments. He retained Wessex to himself. East Anglia was conferred on a chief named Thurchil, who had formerly distinguished himself; and Eric and Edric were continued in Northumberland and Mereia. But the latter shortly afterwards received the full reward of his crimes and perfidy. At a Christmas festival celebrated in London, he had the audacity to boast of his services, when Canute ordered him to be cut down, and his body thrown into the Thames. The Danish king had embraced Christianity, and also taken to wife Emma, widow of Ethelred. The profession of the former removed the main barrier between his English and Danish subjects; and his espousal of a royal female was no doubt intended to conciliate the affections of the Saxons; and it seems to have had a considerable effect in this respect. The other events of this reign will be found related under the head of CANUTE. He died at Shaftesbury in 1035, and was interred at Winchester. By his wife Emma he had a son and daughter; the former called Hardicanute, or Canute the Hardy. But previously to his marriage he had by another lady two sons, named Sweyn and Harold. The former was installed in the sovereignty of Norway, and the latter ascended the throne of England.

Harold was not entitled to the crown; for it had been provided in the marriage settlement of Emma, that the issue of Canute by her alone should reign; yet he being on the spot, succeeded in obtaining the sceptre as well as the treasures of his father. Edward the son of Ethelred, certainly the legitimate sovereign of the kingdom, made an attempt to obtain it, but proved unsuccessful. His brother Alfred renewed the enterprise, which proved fatal to him and to most of his followers. This prince received a letter, which purported to be from his mother, inviting him to come over and take possession of his father's dominions. The proposition was flattering, and in an unlucky moment he yielded to it. Having landed with six hundred followers, he was treacherously made prisoner, along with his companions. Every tenth man was set at liberty, a few more were reserved as slaves, and the remainder were massacred and mutilated with the most capricious cruelty. Prince Alfred himself was deprived of his eyes; and this shocking barbarity soon afterwards terminated in his death. The unfortunate sufferer was the dupe of a forgery; and the whole villanous transaction seems to have been planned by Harold, and executed by his minions, particularly Earl Godwin. This remarkable individual, according to the only account of him which we possess, was the son of a Saxon herdsman. In his youth he had assisted Ulfr, a Danish chieftain, to make his escape to the ships of Canute. The Northman took him under his charge, and by successive steps he rose to the dignity of a Jarl, and to the possession of power little less than sovereign during three reigns. The atrocious deed of blood above related is the only event of importance associated with the name of Harold the First. He died in 1040, and was succeeded by Hardieanute, his brother by the half blood.

This sovereign reigned about two years; and the little that is recorded of him is of a very mixed character. He came over from Denmark, breathing revenge against the murderers of Alfred, and even went so far as brutally to insult the lifeless remains of Harold. Godwin stood prominently forward as an object of punishment, but a splendid present turned aside the shaft of vengeance. Others also escaped by appealing to his avarice, which seems to have been his ruling passion. Edward the son of Ethelred was kindly and honourably received at his court—a noble act of generosity; yet the author of it died of intemperance at the nuptial feast of a Danish lord.

Edward, surnamed the Confessor, the surviving son of Ethelred, was chosen king of England in 1042. He was a weak and feeble prince, and incompetent to the task of vigorous government; yet the commencement of his reign was characterized by an act of severity. He despoiled his mother Emma of her property, and deprived her of her influence. These proceedings were prompted by the antipathy which she bore to the king, and by her lukewarmness in not punishing the murderers of her son Alfred, of whose blood it was even whispered she was not entirely guiltless. The weak and irresolute character of the king threw the power entirely into the hands of the three noblemen who divided the Saxon territory amongst them, Siward earl of Northumberland, Leofrie earl of Mercia, and Godwin earl of Kent, whose daughter, Editha, Edward had been induced to marry. Godwin was by far the most powerful of the three; for besides his own territory in Wessex, his two sons, Sweyn and Harold, held large domains northward of the Thames. In 1051 he at last presumed to bid defiance to his sovereign and son-in-law. Edward, who had sojourned a long time in Normandy, where he was well treated, when he ascended the throne invited the guardians and friends of his youth to accompany him to England. They accordingly flocked to him in great numbers, and received ample preferment. One of them, named Robert, obtained the primacy, at that time the station of highest dignity and power. Amongst those who resorted to England was Eustace count of Boulogne, who had married Edward's sister. At Dover, one of Godwin's towns, a foolish affray took place between the followers of the count and the English. This circumstance gave vent to the popular jealousy of the people against foreigners. Godwin assembled a force, and claimed the surrender of Eustace; but the latter was supported by the king, who ultimately succeeded in driving Godwin and his sons into exile. The star of Godwin seemed now to have fairly set; but just at this moment there arose another of far more disastrous omen to the Saxon line. William duke of Normandy came to England with many of his followers, on a visit to his cousin Edward. He was received with great honour, and loaded with presents when he returned to his own country.

Had the illustrious stranger never risen to be ruler of England, his first visit to it would probably have been passed over by historians with a simple relation of the event. But his singular fortune has induced some writers to find in it a clue to his subsequent proceedings. It is impossible to conjecture what may have passed in his mind upon this occasion. On the one hand he saw, that in the course of a few years, the crown would soon become vacant, for its possessor was now stricken in years, and, moreover, childless. On the other hand, there stood in the way of his claim to it, first of all, Edward, the son of Edmund Ironside; then his son Edgar Atheling, a weak prince, however; and afterwards the brothers of Edward's queen. Under such circumstances his vaulting ambition may have led him to indulge in aspirations to the crown; but only a vague probability of ultimate success must have been awakened in a mind possessed of such high reflecting powers as that of William the Conqueror. Too many obstacles stood in the way of his fostering any sanguine hopes of acceding to the throne of England; and it is certain that the objects of his first visit were pacific. It appears highly probable that his politic foresight might induce him to take measures for securing the crown after the death of Edward the son of Ironside, which took place some years subsequently to his visit to England; and a conjecture may be hazarded that it was immediately after the demise of his brother's son that the Confessor made a promise to William of leaving him the crown. That such a promise was given was afterwards alleged by the Conqueror, as we shall see when he comes before us as a claimant of the sovereignty. In about a year after this the Godwins were restored to their honours and estates; and Editha, who had been repudiated by the king, was called from her prison to the throne. She was innocent of any participation in her father's guilt. The annalists of the time represent her in the most amiable light, and as incapable of devising evil either against her husband or any other individual. On his re-instalment in his earldom and possessions, Godwin succeeded in inducing the king to outlaw Archbishop Robert and all the Frenchmen; and not long after he died ripe in years and in crimes. In 1055 Siward followed him to the grave; and two years afterwards expired Leofric, the wise and powerful duke of Mercia, who was succeeded in his dukedom by his son Algar. Tostig, brother of Harold, received the earldom of the former; but in a few years afterwards (1065), he was deposed for his cruelties, and his sovereignty conferred upon Morcar, son of the Duke of Mercia.

Soon after these transactions, the pacific monarch of England began to sicken. When he saw his end approaching, he ordered the magnificent church of St Peter at Westminster, which he had built, to be consecrated with solemnity and splendour. He died two days after, on the 4th or 5th of January 1066, in the twenty-fourth year of his reign, and was interred in the church which he had so recently dedicated. He left no issue; for he had taken a vow of continence for life. Edward Atheling, the only surviving son of Edmund Ironside, had landed from Hungary with his wife and children, for the purpose of being proclaimed heir to the crown; but shortly after his arrival in London he expired, bequeathing his claim to his son Edgar.

Edward the Confessor presents himself to us only in one character, that of a royal monk. His piety and gentleness might have adorned a cloister, but, unallied with those sterner virtues which fit a monarch for wielding the sceptre with firmness and energy, they rendered him unfit for ruling, except under the influence of able counsel, which he had the good fortune to possess during the greater part of his reign. Abject superstition will unnerve even a strong mind, and to a weak one it imparts a character of childlike feebleness, and forms such an individual as Edward. But he had many amiable qualities, which would have redeemed even greater weaknesses than those with which he is chargeable. He loved his people much; he was averse to the imposition of taxes, some of which he abolished; and his charities were frequent and extensive. His subjects repaid his attentions by lamenting his loss as a national misfortune, and consigning his memory to the veneration of posterity.

The day which witnessed the funeral of Edward, saw the coronation of Harold, the son of Godwin. A report had been circulated that the Confessor had appointed him his successor, which greatly conciliated the chiefs; indeed the only opposition which he experienced was from his own unnatural family. On Edgar Atheling, the last surviving prince of the house of Cerdic, was conferred the earldom of Oxford, in lieu of the crown. Tostig, the brother of the king, was a competitor for the crown. Harold Hardrada, king of Norway, promised him his support, and the politic duke of Normandy did the same. In Flanders he was permitted to raise an army, with which he landed in Northumberland; but he was defeated by Morcar, on whom the earldom of the province had been conferred. The discomfited Tostig fled to Malcolm, king of Scotland, where he was well received. The Caledonian monarch had himself been sheltered at the English court during the usurpation of Macbeth, and was established on the throne of his ancestors by the aid of England. As a grateful return for the attentions he had received in that country, he always readily welcomed the malcontents who fled from it. The arrival of his Norwegian ally recalled Tostig from his exile. They joined forces at the mouth of the Tyne, and marched upon York, in the neighbourhood of which city the Saxon army sustained a defeat. But this was only a prelude to the grand struggle. Harold, the king, notwithstanding the necessity under which he lay of watching the south-eastern extremity of the island from a still more formidable rival, collected a considerable army, and marched with promptitude and secrecy to meet Tostig and his Norwegian ally. So rapid had been the movements of the king that he took the enemy in some degree by surprise. They, however, retired upon Stamford-bridge on the Derwent, where they drew out their line of battle. The contest which ensued was bloody, and long of doubtful issue. For a while the firm array of the Norwegians bade defiance to all the efforts of the English cavalry, which, accustomed to charge in detached masses, fell in this dispersed state almost harmless upon the bristling rampart of Scandinavian spears. The king of Norway, conspicuous by his blue tunic and glittering helmet, made the most heroic exertions; but victory forsook his standard; a fatal dart pierced his throat, and he fell lifeless to the ground. Tostig assumed the command, and after a desperate effort to turn the fortune of the day, he perished, with the flower of the Norwegian army. This victory, which is memorable on account of the dreadful slaughter that distinguished it, was gained on the 25th of September 1066. It must be recorded to the honour of Harold, that twice he offered peace and pardon to his rebellious brother, once before and once during the heat of battle, when the Norwegian had fallen, but both times these offers were refused. Three days after this conflict William duke of Normandy landed in England, and Harold had to prepare for another desperate struggle to retain the crown. It will now be necessary to examine how far the pretensions of the new competitor for it were legitimate.

This celebrated claimant to the sceptre of England was the descendant of Rollo, a renowned Vikingr or Sea-King, who flourished at the beginning of the tenth century. Rognvalldr, the father of Rollo, was one of those earls appointed by Harold Harfager, or the fair-haired, to guard his conquests. He had two sons, Thorer and Rolfr, better known by his more celebrated name of Rollo.[1] The progenitor of William the Conqueror was expelled from his country on account of a violation of the law which forbade freebooters, under pain of death, to destroy cattle on the Norwegian shore. Driven from his paternal shores, he resolved to seek for a kingdom elsewhere; and after much successful valour he succeeded in establishing a Scandinavian state in France. Rollo proved himself a prince worthy of a kingdom, and his acquisition in course of time assumed the name of Normandy. His exertions for the improvement of his dominions, the civilization of the rude Northmen, and the humanizing of their minds to the love of order, justice, and the arts of peace, class him with those illustrious individuals who have proved themselves benefactors of the human race. He died in 931, and was succeeded by his son William. After two others, Robert the Magnificent, or the Devil as he was perhaps more appropriately designated, succeeded. He was father to the duke, who now appears before us as a competitor for the English throne. William was an illegitimate child by a damsel of humble condition, of whom his father was enamoured, but could not wed during the lifetime of his duchess, the sister of Canute. Like their northern progenitors, the nobles of the Norman duke were careless of the distinction between concubinage and wedlock, so that on the death of Robert in 1035, William, although then only eight years of age, was triumphantly placed upon the ducal throne, which he filled with renown for fifty-three years.

The circumstance of numerous Norman barons having settled in England during the reign of Edward the Confessor, who was the grandson of a duke of Normandy, has already been noticed; as also the visit paid by William to the childless monarch. It was afterwards asserted by the Duke of Normandy, that upon one occasion, probably that to which we have already alluded, Edward had bequeathed to him the crown of England. He also alleged a testamentary bequest, as well as Harold. Both were alike destitute of any claim founded on the modern principles of hereditary descent, but both by consanguinity made out a species of right to inherit; William as the grand uncle of Emma the king's mother, and Harold as the king's brother-in-law. The claims of the champions were therefore nearly balanced, and seem to have contented their partizans; the sword alone could decide to whom the real title should belong.

In the mean time the claim of Harold suffered considerably on account of a circumstance which occurred a short time before the demise of the late king. The Saxon had been shipwrecked in France, but obtained leave to proceed to Normandy by alleging that he was intrusted with some communications to Duke William. That prince received him kindly, and imparted to him the hopes which he cherished of obtaining the English crown. He received a promise of aid from Harold, and by an artifice succeeded in making him swear fealty to his cause. Underneath the missal on which the Saxon had sworn were concealed various sacred relics, such as the bones of saints and martyrs, and thus he had unconsciously bound himself by the most solemn oath. When the struggle came, Harold urged the plea of compulsion as releasing him from any obligation to keep his vow. Abhorrence of oath-breakers, however, is characteristic of a superstitious age; and whilst the circumstance materially weakened the cause of Harold, it strengthened in a corresponding degree that of his rival. There is also every reason to believe that it was the principal means of enabling William to obtain from the holy see a declaration in favour of his enterprise. At such a period a bull from the pope was itself worth an army, and this the adventurer not only obtained, but also a consecrated standard, a ring, and a lock of his holiness's hair.

William now set busily to work in preparing the means of offensive aggression. When his purpose was known, he was speedily joined by all the young knights of the neighbouring countries who sought fortune or renown, and by all the freebooters whom the hope of spoil allured to his standard. With an armament more formidable than the western nations had yet witnessed, he accordingly put to sea. Annalists have greatly exaggerated the number of his troops; for altogether they did not probably much exceed twenty-five thousand men. With this army he landed without opposition at Pevensey, in the county of Sussex, as has already been observed. He made no stay at that place, however, but proceeded immediately to Hastings to procure provisions. Harold, apprised of the arrival of his most dreaded enemy, flew to attack him. William, informed of his victory and advance, was counselled by some to remain in his entrenchments, and not to hazard an open engagement. But the mind of the future conqueror was not liable to the agitations of fear. He had thrown his life upon a cast, and was resolved to stand the hazard of the die. In this emergency the conduct of Harold has been severely censured. He appropriated to himself all the spoils of the late battle, which added to his unpopularity; whilst the death of his brother was by common report imputed to him. On his march against William, a considerable portion of his army deserted him, and their place had to be supplied by raw and undisciplined levies. When the two rivals were near enough to interchange messages, the Norman offered Harold the choice of abdication, of single combat, or of appeal to the pope. These propositions being rejected, he was then offered Northumberland for himself, whilst Kent would be conceded to his brother Gurth; but the latter proposal shared the fate of the former one; upon which William declared his intention of giving battle to his rival, whom he looked upon and designated as a liar and a perjured wretch, excommunicated by the holy father. He even expressed astonishment that an individual conscious of such guilt as that with which Harold was chargeable should venture his person in battle. We are told that such a feeling also prevailed in the English army, and that the king was advised by his brothers Gurth and Leofwin to withdraw, whilst they would lead on the battle. Harold, however, only smiled at their apprehensions, and expressed his resolution of commanding the army in person.

---

[1] In the *History of England* by Sir James Mackintosh (vol. i. p. 90), the following sentence occurs:—"One of the sons of Roguevald, called in the Icelandic poems *Hrolpt*, better known to us by the name of Rollo, had, for reasons unknown to our authorities, been excluded from all share in his father's domains, and had no resource but piracy." The reason of his exclusion was in all likelihood his being a younger son. We have already noticed, that amongst the Northmen of this period an absurd law obtained, by which all but the eldest son were excluded from any participation in the property left by the father. By this pernicious arrangement the younger branches of families were driven to seek their fortune upon the sea. It is certain that Roguevald left two sons; it is also next to certain that he would observe the law of the land as it then existed. Now, the question comes to be, which of the two was the first born. There is no direct evidence upon the point, but the circumstance of Thorer's name having always the precedence when the brothers are mentioned together, and also that of Rollo's piratical exploits, whilst there is no mention made of his brother in that capacity, seem to determine the point that the progenitor of a future royal family of England was the youngest son;—and thus the difficulty is explained.

On the morning of Saturday the 14th of October William advanced to the attack of the Saxons, after having solemnly heard mass and received the sacrament. The previous night is also said to have been passed in devotion, whilst songs and revelry resounded throughout the Saxon camp. The spot which Harold had fixed upon for this important contest was a piece of rising ground about eight miles inland from Hastings. It was open towards the south, and was covered at the back by an extensive wood. On the front of the declivity the troops were arranged in one compact mass, in the centre of which floated the royal banner, with the king and his two brothers near it. On an opposite hill stood William in front of his warriors, with the relics upon which Harold had sworn hung round his neck, and the consecrated standard waving by his side. After a short address to animate his soldiers, he advanced upon the enemy, shouting the national war-cry " God is our help;" whilst the cry of " Christ's rood, the holy rood," rose from the adverse ranks. The impetuous onset of the Normans was received by the English with their battle-axes, with which they broke the lances and cut the coats of mail, on which their opponents placed great reliance. The confidence of the Normans began to waver, and the left wing, both horse and foot, actually gave way. With eager rashness the English pursued, and thus exposed themselves to the hazard of being cut off; for William with dauntless fortitude and presence of mind had succeeded in rallying his fugitive bands. The attack was renewed, and again the English repulsed it. The duke had now recourse to an artifice which ultimately proved the destruction of the enemy's army. By a feigned flight he allured a body of them from their strong position, and, whilst the latter too eagerly pursued, he turned upon them with his cavalry, and hewed them in pieces. Twice was this stratagem repeated, and each time with perfect success. Still the main body of the English presented an unbroken rampart of shields, against which the mass of Norman chivalry for a long time was hurled in vain.

During the conflict both leaders gave proofs of personal bravery and skill worthy of the crown which the one was combating to retain and the other to wrench from his grasp. William had three horses killed under him, and hand to hand he had grappled on foot with his adversaries. A little before sunset Harold, both of whose brothers had already fallen, received an arrow in the eye, which penetrated to the brain. His fall relaxed the vigour of the English. Their lines were penetrated, their standard taken; and a panic having seized upon them, they broke and dispersed through the wood, whilst darkness closed upon the spoils of the field and the hopes of the Saxons.

Thus ended the battle of Hastings, memorable in various respects, first, as introducing a new dynasty of monarchs to rule the southern part of Britain; and secondly, as opening up to the inhabitants of the island the means of a more extensive intercourse with the continent than they had ever yet enjoyed. By this means were introduced into Britain those modes of life, manners, customs, and institutions which were at the time considered as characteristic of civilization and refined society; and henceforth England was destined to take a large share in the transactions and fortunes of the continental powers, perhaps ultimately for the mutual benefit of all parties.

On the morning after the battle, the victors, having stripped the bodies of the slain, pranced wantonly over them with their horses. The mother of Harold, like another Andromache, begged the corpse of her son from the conqueror; but whether her maternal request was complied with or not is a matter of great uncertainty; for upon this point our annalists are either contradictory or ambiguous. By one party it is asserted that the corpse of the fallen monarch was interred upon the beach; by another that it was given up when demanded, its weight in gold having been offered as a ransom. Perhaps both are correct; for it is probable enough that it was first buried on the shore, and afterwards exhumated at the request of the mother. Without entering into any speculation connected with the Norman conquest, we may simply remark, that in order to interest the reader of English history, and excite commiseration and pity for Harold, he has, by a number of historians, been invested with talents, virtues, and accomplishments which he did not possess in a degree sufficient to command the entire affection of his countrymen during his life; whilst his death has also been deplored with unnecessary regret, as a sort of national loss. Where the stakes are equal, and the game a fair trial of strength and dexterity, sympathy will always side with the loser. Over his opponent Harold had the advantage of fighting for his native land against a foreign invader; but it must be observed that his own aggrandisement and the independence of the nation were inseparably connected, and that in pursuing the one he was combating for the other.

Before entering into the subsequent history of the conqueror's proceedings, it will be necessary to pause and take a rapid glance at the Anglo-Saxon institutions before they were supplanted by the system which the successful invasion of the Normans was destined to introduce.

The Anglo-Saxon king, without possessing despotic sovereignty, was in dignity, property, and power elevated far above the level of the rest of the nation. He was elected by the assembly called the *wittena-gemote*, a meeting of wise or prudent men. This was the great council of the nation, and seems to have resembled what our modern parliament would be if lords and commons mingled together and debated in one house. It was composed of the prelates, earls, and a great many thanes or considerable proprietors of land, a class similar to our modern gentry; so that the Saxons may be said to have possessed the elements of a free and popular government, though as yet in a rude and chaotic state. This supreme judicial and legislative assembly was convened by the king, and held its meetings on the great festival days of the church, such as Christmas. But these were not confined to such seasons, being called together according as circumstances required. Besides electing the king, and presiding at his coronation, they assisted him in making laws and treaties, in military preparations, in administering justice, and the other affairs of government. Their power was considerable, but it depended in a great measure upon the character and capacity of the sovereign. The highest officer in the kingdom was the ealdorman; he was chief of a shire, and had great judicial powers. An eorl was the next dignity, which remained separate from the former until towards the close of the Anglo-Saxon period, when the title of ealdorman seems to have been superseded by that of eorl; under them were other officers, whom it is unnecessary to particularise. There was of course a wittena-gemote to every kingdom; and when all the principalities merged in Wessex, and gave rise to a single one for the whole country, the monarch occasionally held *shire-gemotes*, or county meetings, where the laws made by the king and his counsellors were proclaimed, and being acknowledged and sworn to, became binding on the whole nation.

The Anglo-Saxons were divided into freemen and slaves. But there was a third class, such as bordars, cottars, and others, who were cultivators of the soil, and, ranking probably in the lowest order of freemen, were scarcely reduced to the degrading level of slaves. As far as has yet been ascertained, the class which was subject to the most complete thraldom was small in comparison with those who enjoyed superior privileges, probably about one in seven. The Anglo-Saxons paid some attention to the cultivation of the land, which was held by various tenures, and liable to certain burdens, which varied in kind and quantity. Military service, which consisted in providing a certain number of armed men when public safety required them, was one of these. The other two great services were the constructing or repairing of bridges, fortresses, and walls. Besides these, the sub-proprietors of land were more or less liable to many other burdens. With regard to their conveyances, we have several of their grants of land without any pecuniary consideration; of their conveyances on purchase; of their deeds of exchange; of their testamentary devises, and their leases. These were, in the early periods of Anglo-Saxon history, short and simple; but in grants of a more recent date the general words are nearly as numerous as in our present deeds.

The supreme legal tribunal was the wittena-gemote, which, like the present House of Lords, was paramount to every other. There were also shire-gemotes and burgh-gemotes, so many yearly meetings of which were strictly enjoined upon those who composed them. Much of their judicial proceedings rested upon oaths, and perjury was therefore severely punished. For the various breaches of the law the punishments were commonly pecuniary. In the case of murder, the amount, which was partly levied by the state as a penalty, and partly granted to the family of the deceased as a satisfaction for the loss of their relative, was proportioned to the rank of the murdered man. Persons accused of crimes had occasionally to pass through an ordeal of hot water or hot iron, of which they had their option.

There were many popular institutions which rendered the king subordinate to the community. The meetings of the people at the various courts, from the folkmote of the hundred, to the wittena-gemote of the nation, contributed to foster the principles of equal law and of popular government. From the Anglo-Saxons we derive our language, the names of the most ancient officers among us, and those of the greater part of the divisions of the kingdom, and of almost all our towns and villages.

In their domestic habits the Anglo-Saxons were social, and loved the pleasures of the table. Their food was that mixture of vegetable and animal diet which always marks the progress of civilization. Ale and mead were their favourite drinks, and wine was an occasional luxury. They had become so far acquainted with the conveniences of civilized life as to display both variety and vanity in adorning their persons. Their dwelling-houses seem to have been small and inconvenient, although they were both expensive and magnificent in their ecclesiastical buildings. Amongst the Anglo-Saxons females were very respectfully treated, and occupied the same independent rank in society which they now enjoy. The trades and mechanical arts had made considerable progress, and even foreign commerce was carried on and considered as a highly honourable calling. With regard to their circulating medium, it may be shortly stated, that they had their pounds, shillings, pence, and farthings, exactly as we have at present. Learning, except amongst ecclesiastics, was neglected; and with regard to literature, little can be said with certainty, for the monuments of this kind which they have left us, except what is historical, have not yet been examined with sufficient care.[1]

The conquest of England did not altogether terminate with the battle of Hastings. London and other important towns were put in a posture of defence, whilst a numerous fleet had assembled at Dover to interrupt the proceedings and distract the attention of the invader. Edgar, the legitimate heir to the throne, appears to have been either crowned or acknowledged as sovereign at London, where the two powerful earls Morcar and Edwin, with the loyal inhabitants, resolved to make a desperate stand against the advancing foe. William, however, instead of attacking the city, chose rather to lay waste the country, which he did most effectually, consigning to the flames what could not be forcibly removed. He now appears before us in a character somewhat new. Formerly he had combated for the crown against an individual who, according to all modern notions of legitimacy, had no more right to it than himself; but in the present instance he was attempting to snatch it from the brow of him who alone had a hereditary claim to wear it. On this account the atrocities committed by his troops are justly contemplated with horror, whilst the disposition to palliate them is proportionally lessened.

William, however, was the candidate favoured by the see of Rome, and the bishops interfered in his behalf. Stigand, the metropolitan, was the first to throw himself on the mercy of William, whom he met as the conqueror crossed the Thames at Wallingford, and swore fealty to him as his sovereign; others followed his example, as did Edgar, Edwin, and Morcar upon the part of the nobility. The crown was offered to him, and he was formally invested with it in Westminster Abbey, on Christmas 1066. During the ceremony a tumult arose which made the stout heart of the conqueror to tremble beneath its iron mail; and, had an English force, led by any competent commander, and capable of making head against the Normans, appeared at the moment, it might have cost him his crown and his life. Whilst, by loud acclamations, both English and Normans expressed their willingness to have William for king, his troops set fire to the houses, and commenced the plunder of the city. The coronation service was hastily concluded, and the insurrection quelled without much difficulty, although the English looked upon it as a bad omen, and William as a most unfortunate occurrence. It was his interest to propitiate the affections of the people whom he had now been appointed to govern, and he anxiously wished to do so. In explanation of this occurrence, it is usually alleged that the Normans mistook the acclamations of those who shouted within the church for an alarm of the English to rise in revolt. But if this had been the case, why did they not instantly fly to the rescue of their king, instead of spreading themselves about and firing and pillaging the city? His safety was surely their first care; for had he fallen, their fate was inevitable. The whole unquestionably originated in the desire of the troops for sack and pillage.[1]

---

[1] Turner's *Anglo-Saxons*, vol. ii. *passim.* Mackintosh's *England*, vol. i. p. 71.

Hitherto William had been called the Bastard; from this period he obtained the surname of the Conqueror, a term which at the time was employed to designate a person who had sought and obtained his right, as well as a subjugator. It was necessary for William to maintain a strong military force in order to compel the obedience of his subjects; and he could only feel himself secure surrounded by his trusty Norman barons. But the duration of their services being limited to a certain term, they naturally expected to be released from their engagements, and re-conveyed to their country, when the period of servitude had expired. In order to encourage them to remain, he put into their hands the strongholds and principal towns of the kingdom, whilst all the conquered territory of the English, which he had at his command, was likewise distributed amongst them. Having thus put his dominions in a secure posture, he embarked for Normandy, carrying along with him Morcar, Edgar, and Edwin, and leaving the chief management of affairs in England in the hands of William Fitzosbern, a Norman baron, and Odo, bishop of Bayeux, the son of his mother by a plebeian husband. During the absence of the Conqueror, the Saxons began to mutter threats of vengeance, and even went so far as to enter into a conspiracy to cut off the Normans as their forefathers had done the Danes. It appears, from the testimony of several credible annalists, that the oppression which the English suffered at the hands of the insolent soldiery was most galling, and called loudly for retaliation. These alarming rumours crossed the channel, and reached the ears of William, who hastened from his continental dominions, and, landing in England in December 1067, made a sort of second conquest of that country. The Saxons of Devonshire, joined by the neighbouring Britons in Cornwall, had thrown off their allegiance to him, and against them he first turned his arms. They made a gallant stand; but William having reduced Exeter, succeeded in breaking the spirit of resistance for a time. About this period, Edgar, with his mother and two sisters, having embarked for Hungary, were driven by a tempest upon the coast of Scotland. That country was at the time governed by Malcolm, surnamed Ceanmore, who gladly received the fugitives, and made them a return for that kindness which he had himself experienced under similar circumstances at the English court. Many Saxon nobles followed Edgar, who, with subsequent emigrations of disaffected Normans, founded the greater number of the Scottish noble families. Malcolm afterwards married Matilda, the eldest sister of Edgar.

William the Conqueror now turned his attention to the north, where his authority had not yet been properly established. From the heart of Mercia to the confines of Scotland a spirit of open insubordination prevailed, and was fostered by Edwin, who had been at one time promised the hand of William's daughter, but was afterwards refused it. The insurrection became formidable; but it was soon quelled, and this served more and more to confirm the power of the Normans. William penetrated as far as York, which opened its gates to him, scattered the isolated and feeble bands who opposed his march, and reduced all the important towns on his way. During this expedition he also fortified a number of castles. The tranquillity thus produced was, however, of short duration. At Durham the English succeeded in massacring the whole Norman force established there, excepting two men. York followed the example of Durham, and rising upon the garrison, killed the governor, with many of his retainers. Shortly after this event, the sons of Harold, the late king, landed from Ireland with the intention of making an effort to recover the crown; but they were utterly defeated in two engagements, by Brian, son of the Earl of Bretagne.

A new and formidable auxiliary of the malcontents had now however arrived in the Humber; this was a powerful Danish armament. Edgar Atheling, several illustrious Saxons, and crowds of the English, having joined them, they successfully assaulted York; but William, apprised of their descent, hastened to the scene of war. His usual good fortune attended him; and the Danes were compelled to quit the country without crossing arms with the Normans in any conflict worthy the name of a battle. Hints have occasionally been thrown out that they were bribed by the Conqueror; but of this circumstance there is no direct evidence. Upon another point, however, all historians are agreed, namely, that, piqued by these repeated insurrections, the king, in a transport of passion, had sworn to extirpate Northumbria. This merciless vow was performed nearly to the letter. Unbounded license was given to the soldiery, who ravaged the country with fire and sword. The destroying angel could scarcely have left a more desolate wilderness behind. An historian, William of Malmesbury, who wrote sixty years after the event, thus describes it: "From York to Durham not one inhabited village remained; fire, slaughter, and desolation made it a vast desert, which continues to this day." The dead remained unburied; famine, with pestilence in its train, stalked throughout the neighbouring provinces; whilst confiscation brought up the rear of this terrible visitation, and completed the ruin of the country and its inhabitants, gleaning whatever the sword had not destroyed. Such atrocities as these imprint a blot upon the escutcheon of William which it is impossible to obliterate. To his authority the rebel chieftains were compelled to submit; and having thus in the most summary manner crushed rebellion in this quarter of his dominions, he returned southwards, clearing the provinces of the disaffected as he proceeded, and repairing or building castles for the subjection of the country.

William was now undisputed master of England. The conquest of the country, properly speaking, only began with the battle of Hastings. It was not until seven years thereafter, when he carried the terror of his arms to York, that the country was completely subdued. Before that period not one half of England acknowledged his authority. But the spirit of the Saxons was now fairly broken, and finding themselves pursued with such extirpating vengeance, many of them sought refuge amongst the hills and forests, whilst others emigrated to foreign lands. A party of them under Hereward, a resolute chief, attempted to make a stand in the island of Ely, immediately after the northern massacre. This land of fens and marshes was the last asylum of Saxon independence; and Morcar, with some bishops and the remainder of the most conspicuous Saxons, repaired thither. For a while William disdained to notice the efforts of Hereward; but at last he invaded his circumscribed territory, and, scattering his little band, compelled him to fly. This bold and patriotic chieftain afterwards gave in his submission, and being allowed to retain his paternal possessions, the end of his days proved happy. His daring exploits had endeared him to his countrymen, and conferred on him a romantic celebrity. His actions were the theme of many a Saxon song; and even the Normans did homage to his warlike virtues. He was the last of the Saxons who drew the sword in the cause of national independence.

---

[1] Although not mentioned by our historians, contemporary annalists establish and illustrate the fact that the armies of the continent at this period were in a great measure composed of mercenaries, who followed war as a profession, and hired themselves out to the best paymaster. These individuals were different from those who followed the banners of the barons according to the feudal system. They were little better than hired banditti, and were very numerous in the Low Countries, whence William had sprung. That the force with which he invaded England contained vast numbers of these condottieri, is not only probable, but appears nearly certain, when we contemplate the methods of furnishing out an army in those days. The plunder of the provinces which they overran or conquered seems to have been looked upon by them as not only allowable, but as forming part of their reward. That the affair at William's coronation arose from their rapacity for pillage, which they looked upon as a right, there can be little doubt; and they chose the most fitting time for successfully carrying their project into execution: a time when their leaders were withdrawn, and in attendance at the ceremony going on within the church. They had previously broken out in the same way at Dover.

William having now quieted the tumults at home, turned his attention to Malcolm, king of Scotland, whom he compelled to submit. The affairs of the church also occupied him for a time; and several changes were effected, not, it may well be believed, to the advantage of the Saxon prelates. One of them, the Archbishop of Canterbury, was deposed, and his place supplied by Lanfranc, who, although a worthy man, was the creature of William, and in bondage to Rome. In the meanwhile, Edgar Atheling had sought and obtained the friendship of the Conqueror, who, to his honour, ever afterwards maintained this weak and almost imbecile youth in ease and affluence at his court.[1] William now ventured upon another visit to Normandy, where we shall leave him engaged in petty contests, and take a view of the state of England after its subjugation.

By the introduction of a foreign sovereign, a foreign hierarchy, and a foreign nobility, the native population suffered severe depression. To supply the liberal grants of land and places of honour and trust to his followers, the English were of course sacrificed; and thus they were compelled to become the servants or dependents of their conquerors. Contempt and oppression became their heritage. Their farms were pillaged, their females violated, their persons imprisoned, and other indignities heaped upon them, at the caprice of the petty tyrants who were set over them. The principal favourites of the Conqueror had another distinction conferred upon them in addition to the grants of land. This was the earldom or command of the several counties. Two legal revolutions occurred or were completed during the reign of William; the separation of the ecclesiastical from the civil judicature, and the introduction or consummation of the feudal system, for an account of which the reader is referred to the proper head. He effected various other judicial changes which were ultimately beneficial to the community. The crown revenues were a continuation of those which the Anglo-Saxon kings enjoyed; but they appear to have been considerably increased by the various changes which took place, and also very carefully collected; for from an ancient historian we learn that the king's daily income amounted to above one thousand pounds, a sum almost incredible when we reflect that gold was then three times and silver ten times the value which they possess in modern times.

During the visit of William to his continental possessions, the Norman barons rebelled against him, and were joined by some Saxon chiefs. The king hastened across seas with a band of auxiliaries, and made an easy conquest of the insurgents. The remaining events of his reign are not sufficiently important to require a minute recital. The most remarkable is the revolt of his son Robert, who had been promised the duchy of Normandy when William first invaded England. The French monarch fomented the hostilities between the father and son, which existed for several years, and closed with a most romantic incident. Robert, being besieged in the castle of Gorberoi, engaged a knight enveloped in complete armour, and unhorsed him, at the same time inflicting a wound in his arm. When about to pursue his advantage, Robert recognised in the fallen warrior the voice of his father. A reconciliation was finally effected by the tears and entreaties of Matilda, the mother of this Norman Absalom.

Whilst engaged in a desolating warfare against Philip, king of France, William came before the town of Montes in July 1087, and ordered it to be burned. He rode to view the scene, and galloping among the smouldering ruins, his horse reared and plunged so violently as severely to wound the rider, who was at the time very corpulent and unwieldy. He was carried in a dangerous state to the vicinity of Rouen, where he breathed his last, on the 9th of September. On his death-bed the conscience of the Conqueror appears to have stung him deeply; for he ordered that several prisoners in England, amongst whom was Odo his half-brother, should be set at large; and that restitution should be made for what he had violently destroyed. But these atonements were inadequate to expiate the crimes of which he had been guilty.

The character of William has been drawn in the Saxon chronicle by an Englishman, who was his contemporary, and lived at his court. From this document we learn that the king was very wise, very rich, and "more worshipfull and strong than any of his fore-gangers." It is added, that "he was mild to good men who loved God, and stark beyond all bounds to those who withstaid his will;" and the chronicler goes on to show that he exercised a passionate as well as politic tyranny. That, in fact, he surpassed his contemporary rulers in capacity for command, the events of his life bear ample testimony. All those qualities which fit an individual for directing and controlling the minds of men in troubled times he possessed in an eminent degree. In extenuation of his perfidy and cruelty, it may be urged that these detestable qualities were not more characteristic of him than of the age in which he lived; and that he is conspicuous for them above his competitors only because, from the vigour of his mind, and the great transactions in which he interested himself, he was their superior in every thing else. In a happier state of society, when moral restraint is generally recognised, and influences the development of the mental constitution of man, his glories would not probably have appeared more stained with blood than those of Cromwell and other warriors who have attained the seat of successful ambition and uneasy power. Neither these palliatives, however, nor his death-bed penitence, can atone for irrevocable crimes, or erase from the page of history such deeds as the Northumbrian massacre.

---

[1] Sir James Mackintosh, in his *History of England* (vol. i. p. 108), gives a somewhat different account of this youth, but upon what authority is not stated; ours is Mr Turner, who quotes from William of Malmesbury. There is considerable ambiguity in the passage; for Sir James (p. 102 of the same work) says that Malcolm Ceanmore "married the Princess Margaret, after the *death of her brother Edgar*." Now the king of Scotland espoused this princess several years before the events noticed in p. 108, so that one or other of these statements must be erroneous; for none of our historians makes mention of *two* contemporary princes named Edgar belonging to the royal house of Wessex.

Much has been written concerning the Norman conquest, for it is a subject of inexhaustible interest. That it became ultimately of incalculable benefit to the country, whatever may have been the suffering immediately consequent upon the event itself, no one can doubt who reflects upon the fluctuating condition of England, its oscillation between foreign bondage and native independence, its internal broils and never-ending distractions, previously to the invasion of the Normans, with the consolidated strength which it internally displayed, and the dignified bearing which it outwardly assumed, after it was conquered by them. Insurrections, though not unknown afterwards, were of less frequent occurrence, and far less alarming, than before; and from the period of the invasion of William, no foreign enemy dared to set his foot upon the soil with impunity. Amongst the financial innovations of his reign was the composition of the Doomsday Book, for an account of which the reader is referred to the article under that head.

The Conqueror left three sons by his wife Matilda. Robert, the eldest, was installed in the duchy of Normandy; whilst William, surnamed Rufus or the Red, from his complexion, obtained the throne of England, and was crowned on the 26th of September 1087. An attempt was made by his half-uncle Odo to dethrone him, and to set up his brother Robert in his stead. But William, alarmed at the formidable demonstrations which were made against him, appealed to the English for aid, and his call was most loyally obeyed. The Normans who had invaded England were compelled to fly, and William carried the war into Normandy, where a reconciliation was effected in the year 1091. The king of England had acquired several continental fortresses, of which he was still to retain possession. It was also stipulated between the brothers, that on the decease of either, the survivor should succeed to the dominions of the other. Henry, the younger brother, who suffered by the treaty, held out several strong places in Normandy; but they joined their forces together, and besieged him in St Michael's Mount, whence he was compelled to fly from want of water.

Robert accompanied his brother to England, where he had been promised possessions as an equivalent for the fortresses which he had yielded up in Normandy. But William did not find it convenient to fulfil the terms of the treaty; upon which his brother, who had again crossed the channel, sent over two heralds for the purpose of declaring him a false and perjured knight. In order to defend his honour, the king followed them into Normandy; but his transactions there belong rather to his own individual history than to that of the country which he governed. The possession of his brother's dominions was a leading object of William's ambition; and he gradually acquired an ascendency in Normandy, which he repeatedly invaded, obtaining new cessions at each adventure. Robert finally mortgaged the whole country to him for three years, at an equivalent of ten thousand merks.

The other events of William's reign were, an invasion of Wales, which was crowned with the usual success; and a war with Scotland, in which the monarch of that country was slain. His government of England was most unpopular. For the gratification of his own appetites, and the enriching of worthless favourites, he plundered the country with impunity. During the life of Lanfranc, his undisciplined rapacity was checked by the wisdom and influence of that excellent prelate. His death, however, removed every restraint, for the king supplied his place by the appointment of an able but remorseless counsellor, who, according to the king himself, was capable of braving the execrations and the vengeance of mankind, in order to gratify his master's desires. Many bishoprics, including amongst these the see of Canterbury, were kept vacant by the king for several years, until a severe illness convinced him of the necessity of appointing a primate. The individual whom he fixed upon was Anselm, one of the most learned and meritorious men of his age. This individual at first demurred to accept the archbishopric, dreading the violence of the king; but the earnest solicitations of his friends at last induced him to comply, and he thus became primate of England. William, as long as his illness was of a dangerous character, showed himself penitent and submissive. He commanded all his prisoners to be released, all his debtors to be forgiven, and all offences to be remitted; and he solemnly vowed that if he recovered he would govern the land in righteousness. But no sooner was he convalescent than he showed that his profession of amendment was only a matter of convenience, and extorted from an unforgiving spirit by the terrors of death. Anselm, as was usual in such cases, brought a voluntary present to his master as an acknowledgment for the dignity which had been conferred upon him; but the gift, not corresponding to the avaricious views of the monarch, was refused, and the unfortunate primate was ever afterwards persecuted by him with the most unrelenting tyranny. Anselm at last sought shelter in Rome, where he continued until William's demise.

The death of the monarch, like his life, was violent. Whilst hunting in the New Forest, he was accidentally struck by an arrow, which buried itself in his breast, and he expired on the spot. The shaft is believed to have been shot at random, and to have come from the bow of Walter Tyrrel, a French knight, who immediately made his escape. This event happened on the 2d of August in the year 1100.

Henry the First, surnamed Beauclerk or the Scholar, ascended the throne of England three days after the death of his brother, the preceding monarch. The compact which had been made between William and Robert was set aside; but the latter, considering himself as aggrieved, invaded England. The formidable demonstrations made by his brother, however, intimidated him, and a pacification was at last effected at the accession of Henry; and the latter propitiated the favour of his subjects by many wise acts. He removed the unpopular agents of his unfortunate brother, particularly Flambard, the obnoxious minister formerly alluded to, and also abolished the oppressive exactions which the latter had enforced. Anselm was recalled, and the clergy conciliated, whilst the people had restored to them the Anglo-Saxon laws and privileges as amended by Henry's father. He also gratified the nation by espousing Matilda, or Maud, daughter of Malcolm, king of Scotland, by Margaret, the sister of Edgar Atheling.

The king now turned his attention to the punishment of the outlaws who had thrown off his authority. Amongst these were included several noblemen, and particularly Robert de Belesme, the most powerful subject in England, and a man haughty, rapacious, and deceitful. He had secured himself within the walls of Shrewsbury, but at the arrival of Henry before this place he made a humiliating surrender, upon which his life was spared, but he was condemned to perpetual exile. Some time after these events Robert unexpectedly arrived in England, where he was received with apparent affection by his brother, but very soon discovered that he was in reality a captive. The purpose of his visit was to intercede with Henry in favour of the rebels; but instead of compounding for their liberation, he was reduced to solicit his own, which he obtained by consenting to pay an annuity of three thousand merks. After his return to Normandy he entered into terms of friendship with the outlaw Belesme, who possessed numerous castles in the country. Intelligence of this having reached Henry, he renounced the alliance by which he had bound himself to keep the peace with Robert. This compact was similar to that which had subsisted between William and Robert, and a second time the latter became a brother's dupe. Henry invaded Normandy, and a decisive conflict before the walls of Tinchebrai, on the 27th of April 1106, decided the fate of Robert. His army was completely routed, and he himself taken prisoner and sent to England, where he remained in close confinement till his death, which happened in 1135. The cruel fate of this prince has served as a foil to the virtues which he possessed, and shed over them an artificial or spurious lustre. There can be no doubt, however, that his qualities as a warrior were brilliant, and his mind would seem to have been forgiving and conciliatory. Perhaps an amiable weakness in the latter respect was the ultimate cause of his misfortunes. Amongst the prisoners taken at Tinchebrai was Edgar Atheling. Either from his inherent weakness precluding any thing like fear on his account, or from a desire to retain the golden opinions of the Saxons, Henry pardoned him, and from this period the descendant of Alfred intrudes himself no more upon the page of English history.

Robert had a son about five years of age named William, whom a faithful vassal succeeded in conveying to the French court. As the age of this prince advanced, the hopes of his partizans proportionally increased. Henry, after obtaining possession of Normandy, had succeeded in tranquillizing it, and restoring peace and order; but as his nephew grew up, the claims which he possessed to the duchy of his father became more and more popular, and disturbed the quiet both of his uncle and the country. Henry should have at once yielded his paternal inheritance to the young prince; and the withholding of it was an act of injustice which harassed his life and dishonoured his name. The Norman barons, along with the king of France, took part with the injured youth; but this coalition terminated with the battle of Brenville, which was fought in the year 1119. Louis, the French king, had four hundred, and Henry of England five hundred knights. Both princes displayed great bravery during the engagement, which ended, with comparatively but little bloodshed, in favour of the English. William of Normandy made his escape; and the pope, who paid a visit to Henry at Gisors, effected a reconciliation between him and Louis, without touching upon the main cause of quarrel, namely, the difference between the English monarch and his brother Robert, or rather his nephew William, the father being now politically dead.

Matters having been once more pacifically arranged, and the ambition of Henry gratified, he set sail for England towards the end of November 1120. Upon this occasion a most calamitous event occurred in his family, namely, the loss of his only son William. The prince, with a large retinue of gay young knights and noblemen, embarked shortly after his father. Festivity, riot, and intoxication prevailed on board; but in the midst of this feasting and debauchery, the care of the vessel being forgotten altogether, she struck upon a rock near Harfleur, and went down. Of three hundred individuals who were on board, only one escaped to record the dismal fate of his companions. Prince William would have been saved but for the shrieks of his natural sister, which recalled him to the wreck with the boat in which he was proceeding towards shore; and it sunk under the multitudes who crowded into it.

This sudden calamity revived the hopes of Henry's nephew William, and disturbed all the arrangements of the king in Normandy. A new war was kindled in that country; but it terminated in 1124 in favour of the English monarch. The discomfited youth, however, received a new favour of fortune. Louis of France bestowed upon him the hand of his sister-in-law; and along with her he received several of the provinces nearest to Paris, which had been united to Normandy by conquest. Soon afterwards he was invested with the earldom of Flanders, which had been left vacant by the assassination of Charles the Good in 1127. In the meanwhile, Henry had endeavoured to perpetuate the succession in his own family, by marrying a second time, after the death of Matilda, his first wife, who had brought him a son and daughter. The premature fate of the former we have already noticed; and the latter, named Matilda, had espoused the Emperor of Germany. The marriage of the king proved to be without issue; and his daughter having recently become a widow, was invited to England, for the purpose of settling upon her the succession to the throne. In a general assembly of the prelates and chief tenants of the crown she was proposed by her father and acknowledged by the meeting as heiress presumptive; and shortly after this transaction her father privately married her to the Count of Anjou. This secret negociation drew forth loud complaints from the barons; and many of them declared that the duplicity of the king had released them from the obligation of their oath. This doubtless disturbed the serenity of the king's reign; but another and more important cause of disquietude arose from the increasing power and fame of his nephew in Flanders. However, the death of that prince soon afterwards removed all uneasiness on his account, and restored at least the prospect of tranquillity. But this was not realized; for a quarrel with his son-in-law retained him in Normandy, and embroiled the last years of his reign, which was now drawing towards a close. Robert, the unfortunate duke of Normandy, died at Cardiff Castle in Wales, in the eightieth year of his age and twenty-eighth of his captivity, a great part of which had been spent in total blindness; for an unsuccessful attempt to escape had provoked his brother to deprive him of sight. All the historians of the period do not mention this circumstance, and some state that the prisoner enjoyed every indulgence; so that the point is doubtful, and for the honour of humanity we leave it in this state. In about a year thereafter, he was followed to the grave by king Henry, who died of a surfeit of lampreys, on the 1st of December 1135, in the sixty-seventh year of his age and thirty-fifth of his reign.

The character of Henry has been drawn by both friends and enemies, his contemporaries. The former extol him as wise, rich, and brave; and the latter execrate him as cruel, avaricious, and incontinent. By joining the two characters together, we will form a pretty fair estimate of the monarch. He was undoubtedly an able statesman and a courageous soldier, whilst his resolute attack upon the popular system of rapine which disgraced Europe at the time is entitled to very high praise. He punished offences severely; but his administration of justice was highly beneficial to the country; and hence arose his title of the Lion of Justice. On the other hand, the immorality of his private life, his exactions, his cruelty to his brother and others; his dissimulation, for even his favourites distrusted him; and his avarice, for he hoarded gold like a miser; render his character exceedingly equivocal as a man, whatever estimate we may form of him as a sovereign. His reign offers little worthy of praise, excepting what has been noticed above. It was moreover so agitated, that he passed only five years of untroubled tranquillity in England.

It was the darling plan of Henry that his beloved daughter Maud should be his successor. By her second husband she had three sons, one or other of whom their uncle no doubt looked upon as the future monarch of England. But the claims of the ex-empress of Germany were waived, and Stephen earl of Boulogne, son of Adela, the daughter of William the Conqueror, succeeded to the throne. He was crowned upon the 26th of December 1135, and soon made himself very popular. According to custom, he immediately issued a charter, which promised of course good government and ample redress of grievances. His courts at the solemn festivals were held with extraordinary magnificence. He repulsed the invasion of David king of Scotland, who received a severe defeat at the Battle of the Standard, which was fought near Northallerton; he subdued his enemies in Normandy; and, by a yearly pension, he pacified the husband of the lady whom he had supplanted upon the throne. Robert earl of Gloucester, natural son of Henry, and the great supporter of Maud's rights, perceiving all hostility to be unavailing, at last swore fealty to the king. For the first two or three years of his reign, Stephen sat secure upon the throne; but he was doomed to be overtaken by a series of calamities. These arose partly from the inevitable consequences of his usurpation, and partly from his defects as a sovereign. That passion for depredation and conflict which the preceding monarch had subdued, again broke out. Every one built his own castle and maintained his own band of mercenary ruffians, who sallied forth day and night to plunder the surrounding country, and drag into dungeons such as they expected would give a high ransom for their freedom. A contemporary chronicler has drawn a horrible picture of the atrocities thus committed with impunity; for the mildness of Stephen's character, and probably the recollection of his own conduct in obtaining the crown, induced him to be forbearing and indulgent. His popularity rapidly declined; and in the fourth year of his reign it appears to have altogether ceased. In 1139 Matilda, with a few attendants, landed in England, for the purpose of recovering her lost inheritance. She was joined by Robert earl of Gloucester, with a hundred and fifty knights, who commenced a warfare which nearly hurled Stephen from the throne. After many conflicts, which were only characterized by the misery attendant upon them, the army of the Empress Matilda or Maud defeated that of Stephen near Lincoln, in the year 1141. The king was captured after a brave resistance; and Matilda was soon afterwards crowned queen of England at Winchester. The clergy, although they countenanced the accession of Stephen, now acknowledged her prior claim; and the queen, proceeding to London, was joyfully hailed by the citizens.

But her popularity was of short duration. By her arrogance and contemptuous conduct towards the friends of Stephen, she soon alienated the affections of the people, and was at last compelled to fly from the city and to establish her head-quarters at Oxford. In one of the numerous struggles which followed, the Earl of Gloucester was taken prisoner, which put the fortunes of the belligerents nearly upon a level. The king and the earl were exchanged for each other; and as both parties had now a commander upon whom they could depend, the conflict was perpetuated, with increasing misery to the nation. For some years the balance of power hung nearly in equipoise between them. Stephen reduced Oxford, but Robert defeated him at Wilton; and this miserable warfare continued, until, on the death of her brother Robert, Matilda returned to Normandy in 1147, when a breathing time of two years intervened.

In the meanwhile Henry, the son of Matilda, was advancing in years and in fortune. By his uncle David, king of Scotland, he had been knighted at the age of sixteen; a year thereafter he obtained from his father the cession of the duchy of Normandy; and at the death of that prince he succeeded to the earldom of Anjou. In 1152, by a politic marriage, he annexed the extensive duchy of Aquitaine to his dominions. This aggrandizement of her son's power having elevated the hopes of Matilda and those of her partizans, Prince Henry landed in England; but in consequence of the death of Eustace, the oldest son of Stephen, the two parties agreed to terms of peace. Stephen adopted Henry, and appointed him as his successor, one of the best acts of his troubled reign. They lived in harmony with each other for about a year, when Stephen died on the 25th of October 1154. He reigned nineteen years, during the greater part of which time England exhibited a scene of misery unequalled since the invasion of the Danes. The cause of these calamities we have already alluded to. The character of Stephen is not so deeply stained with atrocities as that of some of his predecessors, probably because it was not so determined. In comparison with them, the grasp which he held of the sceptre was as feeble as his right to seize it at all was equivocal.

Henry II. or Plantagenet, the son of Matilda, ascended the throne without a dissenting murmur. He was crowned, along with his queen Eleanor, at Westminster, on the 19th of December 1154, in presence of an immense concourse of people. The prospect which opened up to this young sovereign was more glorious than that of any of his forerunners in England, or his contemporaries in other countries. An unprecedented mass of power was concentrated in his hands. A third part of France, including almost the whole western coast from the borders of Picardy to the mountains of Navarre, acknowledged his authority. These possessions, along with England, comprehended the most warlike portion of Europe; and had the ambition of the individual who ruled over them been commensurate with his power, the humiliation, if not entire subjugation, of France would not have been reserved for the Henries and Edwards of after times. Although by no means destitute of a passion for power, Henry possessed a love of literature, which led him to eschew the cloudy and troubled atmosphere of war. The civil discord which prevailed during the reign of his predecessor had inflicted numerous evils on the nation, and to the alleviation of these Henry devoted the first years of his reign. He issued a new coinage, of standard weight and purity; he drove beyond seas the foreign mercenaries who had harboured in England during the reign of Stephen; he seized the royal castles which had been usurped, and demolished those which had been reared for the purpose of systematic plunder. By these vigorous steps of reformation Henry secured the effective administration of justice in his English dominions. One of the leading features of his character was restless activity. On foot or on horseback he was perpetually in motion; and the moments which he could spare from more important concerns were usually devoted to the chase.

Some of the leading events of Henry's reign are associated with the name of Thomas a Becket, who has been portrayed as a saint and martyr, or a hypocrite and traitor, according to the religious bias of the historian who happened to draw the picture. Under the article **Becket** an account of this celebrated prelate will be found; and it is only necessary in this place to allude to those events of his life which are identified with the history of his country. One of Henry's first measures was the promotion of this individual to the chancellorship of England, in which capacity he vigorously seconded the measures of reform which the king had undertaken. His administration has been characterized as alike beneficial to the country and to the sovereign, who loaded his favourite minister with honours and emoluments. By the advice of Becket, Henry proposed a treaty of marriage between his eldest son and the daughter of Louis king of France. On this occasion the chancellor undertook a journey to Paris, displaying upon the occasion a pomp and parade transcendently elaborate. Henry himself followed; and although a rupture ensued between the sovereigns about the city of Toulouse, which belonged of right to the king of England, their enmities terminated with the marriage of their children whilst the infants were as yet in the cradle. We have now arrived at that period of Becket's life in which his conduct has been the subject of a kind of historical crusade. In 1161 Theobald the archbishop of Canterbury died, and Becket was recommended as his successor by the king. The clergy of England, however, resisted the nomination, declaring it to be unseemly for a man who was rather a soldier than a priest, and whose life had been devoted to hunting and falconry, to be appointed an archbishop. More than twelve months elapsed between the nomination and appointment, during which time Becket still retained the chancellorship, and evinced no change in his feelings or way of living, which was eminently worldly. He even went so far as to smile at the idea of metamorphosing the gay and pompous Chancellor of England into the Archbishop of Canterbury; and he appears himself to have thought that the choice arose from Henry's confidence that he would become the pliable instrument of his will in ecclesiastical affairs. If the king anticipated such a consummation, never were the hopes of man more miserably disappointed. For no sooner was Becket invested with the primacy, than a change took place in his manners, more strongly contrasted with his former life than were the two offices which he had held. Instead of a train, which in splendour and fastidious pomp had rivalled the retinue of kings, he chose a few monks the most conspicuous for their humility and mortification. Instead of the oriental magnificence and gorgeousness of apparel with which he loved to dazzle the eyes even of courtiers, he selected as his chosen garment the roughest sackcloth. His sports and revels were exchanged for deeds of penitence and humiliation. And thus far his conduct appears to have been commendable; but did his future behaviour warrant a belief that this sudden change was attributable to the sincere conviction of a pure and lofty spirit, which had changed its views regarding the relative value of earthly and heavenly things, or to the policy of a deep and designing hypocrite? The remaining particulars of his life will best enable the reader to form his own judgment as to this, which is one of the most disputed points in our history.

The first step which Becket took after his promotion was to return the seals of his former office to Henry, on the ground of his incompetency to hold two such offices. This measure is said to have at first excited the indignation of the king, who had never before heard Becket object to the prelacy on that account. But it was not until 1163, when hostilities commenced between the church and the state, that Becket and the king came fairly into collision. Previously to the Norman conquest, ecclesiastical affairs had, like others, been decided before the hundred, with the addition of the metropolitan sitting as one of the judges. The Conqueror, however, had instituted a separate tribunal, where the clergy were judged by a court composed of themselves, and from that time they were independent of secular jurisdiction. Becket upheld this claim with firmness, as he ought to have done, until it was formally set aside by the king and his counsellors. This, however, did not justify the decisions which were pronounced, and which had now become notoriously partial. Crimes of the darkest description had frequently been perpetrated by ecclesiastics with the most scandalous impunity; for the judges could not inflict capital, nor indeed any adequate punishment. An abominable instance of seduction having attracted the notice of the king, he determined that those chargeable with such atrocities should be tried before the criminal tribunals of the state. For this purpose he summoned a great council at Westminster, where he demanded that ecclesiastics, whenever convicted of such offences, should be degraded, and handed over to a secular justiciary. His question was, Would they agree to observe the ancient customs of the realm? Becket answered yes, saving his order; an ambiguous reply, which was echoed by the conclave of bishops present, with only one exception. But, although not at this assembly, he was afterwards compelled to yield the point without any reservation respecting his order. This formal assent was obtained at the celebrated council of Clarendon, which took place on the 25th of January 1164. At this great or common council of the realm, for the word parliament had not yet been introduced, Becket was compelled to yield compliance to the demands of his sovereign. At first he peremptorily refused his acquiescence; but the king, incensed at his obstinacy, menaced him with exile or death, whilst several individuals of rank present entreated him with genuflections and tears to submit; by which means a compliance was at last reluctantly wrung from him. These customs and usages, the recognition of which was thus so vehemently urged, were contained in sixteen articles, which were afterwards well known under the name of the Institutions of Clarendon, by which it was enacted that clergymen accused of any crime should be tried in civil courts; that laymen should not be tried in spiritual courts, except by legal and reputable witnesses; that no ecclesiastical person should quit the realm without the king's license; that all causes not ecclesiastical should be finally determined in the king's court; that all ecclesiastical persons who were tenants *in capite* of the crown should follow the king's customs, sue and be sued respecting their fiefs before his justices, and attend, like other barons, at his courts; that vacant dignities in the church should be in the king's hands; and that he should also receive the profits of his seignorial dues. These, with some others, to the number of sixteen, were subscribed by all the ecclesiastics present, including Becket himself. He was now not only mortified in the highest degree, but, pretending extreme contrition for what he had done, did open penance for his supposed delinquency. He attempted to make his escape to France, but was arrested for an offence against the institutions which he had recently signed. Henry was now exasperated beyond all bounds at the archbishop, and assembled a parliament at Northampton, obviously for the purpose of crushing him. Becket was accordingly summoned to account for rents and profits connected with his primacy. He arrayed himself in his sacerdotal vestments, and, with the cross in his hand, proceeded to the place appointed. The king complained to the council of the insolent behaviour of Becket, and the whole assembly joined in condemning his inconsistency. The suit regarding rents, which was only intended as a menace, he attempted to free himself from, by pleading a release by Henry the king's son; but this was overruled. After being condemned as a perjured traitor, he left the palace, his eyes fixed upon the cross, which he held uplifted in his hands; and, travelling in disguise, he

History.

reached the port of Sandwich, whence he immediately embarked for the Continent.

Becket was received with marks of esteem by the king of France, and likewise by the pope, whose cause he had so strenuously defended in England. When Henry learned the flattering reception which the obnoxious exile had received, he dispatched an embassy to expostulate with Louis, and sent another to Rome, to justify his conduct to the pontiff. But the ambassadors were received with coolness, if not with something which bordered upon contempt. The judgment of the barons and bishops was annulled by the pope, and those who should invade the property of the church were declared to be cut off from the society of the faithful. Henry's irritation had now reached its climax, and he resolved upon taking a bold step, which, had the human mind been ripe for such a measure, might have ended in the separation of the English church from that of Rome; but this achievement was reserved for the Henry of a future day. He gave orders to his justiciaries, prohibiting, under severe penalties, all appeals to the pope or the archbishop, and forbidding any person to receive mandates from them, or to apply to their authority; and he declared it treasonable to bring over from either any interdict against the kingdom. On the other hand, the pope was not slow in issuing his fulminations. Becket was ordered to excommunicate Henry's chief ministers, and put the see of Canterbury, including about three fourths of the kingdom, under an interdict. But Henry stood firm, and looked with indifference upon the papal lightnings which played around him. At last, however, he began to dread the powers of his victim, chiefly on account of his continental dominions, and proposed a reconciliation. The treaty of accommodation, although more than once broken off, was finally concluded, and Becket returned to the see of Canterbury without having been compelled to make any express submission to the institutions of Clarendon.

But the wounds had been too deep to be thus suddenly healed, and, though closed at the surface, the venom still rankled underneath. The arrogance and presumption of the primate returned along with his dignity. He refused compliance with the terms of the general amnesty, and would not submit to take the oath of homage for his baronry; neither would he withdraw the whole of the ecclesiastical censure from the prelates who lay under it on account of their obedience to the king's commands. Several very imprudent excommunications soon followed, and so provoked Henry that he is said to have dropped certain passionate expressions, intimating something which was interpreted into a desire that Becket's life might be taken away. The supposed will of the king was instantly accomplished by four knights of distinguished rank, who repaired to the church of Canterbury, where the primate then officiated, and barbarously slew him at the foot of the altar. See BECKET.

Thus perished by foul murder, in the fifty-third year of his age, Thomas a Becket, who, every thing considered, was probably the most remarkable man of his time. That he believed he was all the while conscientiously performing his duty, in preserving the immunities of the church, there seems little reason to doubt; for he would not have met his fate with such heroic and martyr-like firmness unless this had been the case. His virtues were of an austere character, and wanted that amiable attractiveness which we usually associate with the character of one who is profoundly inspired by the morality of the gospel. His vices, on the other hand, were the reverse of mean and grovelling; for his spirit was lofty and aspiring, and his designs were invested with a dazzling grandeur, and pursued with a fearless firmness much more calculated to excite awe than detestation, far less contempt. That Henry did not intend the murder of Becket, appears certain from his subsequent conduct. He was thrown into the utmost consternation on hearing of it, knowing well that the primate's death would accomplish what his most violent opposition during his lifetime could never have effected. He abandoned himself to sorrow and mortification, and for some time refused to take any nourishment. The pope was with some difficulty made sensible of the king's innocence; but declined to grant him a pardon, except on condition that he should make every future submission, and perform every injunction which the holy see thought proper to prescribe or impose. He was likewise enjoined to perform a humiliating penance at the tomb of Becket, who was in due time canonized as a saint and venerated as a martyr. The assassins, despairing of pardon, sought refuge in a distant castle. By the pope they were enjoined to make a pilgrimage to the Holy Land, where they all died, and were buried before the gate of the temple at Jerusalem.

History.

We come now to a very important event in the reign of Henry II. that is, the annexation of Ireland to the English crown; but the details of his invasion it is unnecessary to relate here, as they will come in due order to be treated of under the head IRELAND.

The king was scarcely freed from the Irish war, and the dangerous controversy in which he had engaged with the church of Rome, when he found himself involved in the most unnatural contests with his own children, to whom he had always behaved in the most tender and affectionate manner. He had ordered Henry, his eldest son, to be anointed king; and he had destined that prince as his successor in the kingdom of England, the duchy of Normandy, and the counties of Anjou, Maine, and Touraine, territories which lay contiguous, and which might thus easily afford mutual assistance to each other when necessity required. Richard, his second son, was invested with the duchy of Guienne and the county of Poitou; Geoffrey, his third son, inherited, in right of his wife, the duchy of Brittany; and the new conquest of Ireland was destined for John, his fourth and youngest son. The last sixteen years of Henry's life were embittered by family hostilities. A mighty confederacy was secretly formed against him, in which his three eldest sons participated. Louis VII. king of France, fed the discord; for the power of the English monarch had now become so formidable as to excite alarm and kindle up jealousy in the breasts of the continental sovereigns. The young prince was persuaded to demand of his father some of the dominions which he had been promised, and of which he was nominal sovereign; but he was refused. Upon this the prince made his escape, and put himself under the protection of the king of France. The French monarch then invaded Normandy; and Richard and Geoffrey, the sons of King Henry, severally raised the standard of revolt in Guienne and Bretagne. William the Lion, king of Scotland, considering this as a favourable opportunity for invading England, advanced into the northern counties, destroying all he met with. A great force of foreign mercenaries, called Brabançons, landed in Sussex, under the command of the Earl of Leicester, whilst Prince Henry collected another army in France in order to co-operate with them. To meet this formidable coalition against his authority, King Henry made the best preparations which circumstances admitted of; and if we may judge of these by the results which followed, he must have taxed his constitutional activity to the utmost in collecting forces, and in opposing a barrier to the tide of war which thus rolled onward from every quarter, threatening to overwhelm his throne. Few of his own barons could be depended upon, and he had recourse to the foreign mercenaries so largely employed by his adversaries. Twenty thousand of these auxiliaries enlisted under his banners, and with them were united such of his own nobles and retainers as could be trusted.

The enmity of the young princes against their father had been in no inconsiderable degree excited and fostered by Eleanor their mother, whom the incontinent and licentious life of Henry had for ever estranged from her affections. She attempted to make her escape; but was taken prisoner, and consigned to close imprisonment, where, with the exception of a short interval, she remained till the death of her husband.

In the meanwhile, the plan devised by the allies began to be acted upon, as already indicated; but Henry of England proved himself superior to the emergency. His foreign enemies were on all sides discomfited, and William of Scotland having accidentally fallen into the hands of Henry, the Scottish army broke up and dispersed. Their sovereign afterwards obtained his freedom by the humiliating surrender of his authority as king of Scotland; for conceding to Henry the title of lord paramount of his kingdom was virtually casting his crown at the feet of his enemy. A pacification was brought about at Falaise, on the 28th of September 1174, by which the princes were pardoned and enriched with new liberalities.

King Henry, however, was permitted to enjoy but a few years of repose. The dissensions between him and his children again broke out. The latter also quarrelled amongst themselves, and a most unnatural war ensued, in which neither party gave quarter. But the death of Henry, the eldest son, for a time suspended these disputes. This unfortunate prince died in 1183, of a fever brought on by vexation and fatigue. Three years afterwards Geoffrey perished beneath the feet of a horse in a tournament at Paris, so that the subjects of discord were diminished. The widow of Geoffrey, soon after his decease, was delivered of a son, who was named Arthur, and invested with the duchy of Brittany, under the guardianship of his grandfather, who, as duke of Normandy, was also suzerain lord of that territory. Philip, as lord paramount, disputed the title of the English king to this wardship; but he was obliged to yield to the wishes of the Bretons, who preferred the government of Henry. Some other causes inflamed the dissension between these monarchs, and Philip once more seduced Richard from his duty. He insisted that the marriage of that prince with Adelais, his sister, should be immediately completed, and threatened to enforce his demands with a formidable army. This lady had been confined for a long time in a castle by Henry, who procrastinated the nuptials, until a suspicion arose that he intended to appropriate her to himself. At the conclusion of the truce which had followed the death of Geoffrey, Richard finally forsook his father, and did homage to the king of France for his continental dominions.

For some time the eyes of the monarchs of Christendom had been turned to Palestine, which the Sultan Saladin was overrunning with his mighty hosts. Henry of England was desirous of taking the cross and proceeding to Syria, but his perpetual contests with his family detained him until the holy city was taken by the infidels. The news of this event awakened feelings of regret and indignation throughout Christendom. The Emperor of Germany marched his bravest knights towards Asia. Philip of France and Henry agreed to follow, but the union of the former with Richard the son of the latter compelled the king of England, in the first place, to look to the defence of his own territories, which were once more invaded by the confederates. The war proved very unfortunate for Henry, who lost several towns, and very narrowly escaped falling into the hands of the enemy. A treaty was at length agreed to, but the terms of it were very humiliating to the English monarch. With a heart overwhelmed with grief, he returned to the castle of Chinon, where he soon afterwards expired, on the 6th of July 1189, in the thirty-fifth year of his reign and the fifty-seventh of his age. Upon his death-bed he was sedulously attended by one of his natural sons, the fruit of an amour with Rosamond, whom popular romance and tradition have surnamed the Fair, and invested with every virtue but one. Henry was interred with little pomp in the convent of Fontevraud, in the presence of his rebellious son Richard, and a few knights; but Eleanor, his queen, survived him many years, having been liberated by her son Richard. The character of Henry II. has been already detailed at sufficient length. During his reign important changes in ancient law and usage were matured, and became conspicuous, on which account they have been ascribed to the administration of this monarch; but it is more probable that they resulted from the slow growth of circumstances, with little aid from rulers, who were perhaps unconscious that any change had occurred.[1]

Richard I. succeeded to the throne without opposition, and was crowned on the 3d of September 1189. The reign of this monarch, the Achilles of modern Europe, is interwoven with events which are more akin to romance than to real history. His life is made up of the adventures of a knight-errant. His character was a singular compound of qualities noble and mean; of the grand and the grovelling, the sublime and the grotesque. It has been thus drawn by Mr Turner, in his *History of England:* "Haughty, irascible, and vindictive, a towering and barbaric grandeur, verging sometimes into barbarian cruelty, distinguished his actions. Valiant beyond the common measure of human daring, unparalleled in his feats of prowess; inferior to no man in hardihood, strength, and agility; stern and inflexible in his temper; rapacious and selfish, yet frequently liberal to profusion; gorgeous to ostentation, yet often gay, familiar, satirical, and jocular; unshaken by adversity; resolute to obstinacy, furious in warfare, fond of battle, and always irresistibly victorious; his life seems rather the fiction of a poet's imagination than the sober portrait of authentic history." But this character for martial prowess and heroism was softened by a love of literature, particularly Provençal poetry; and although the specimens of his compositions which have been transmitted to us scarcely deserve the name of poetry, still they evince the presence of the passion in his mind. It was the same sentiment which thus penetrated the tempestuous atmosphere so congenial to his soul that imbued his exploits with the spirit of genius and romance. An overweening love of praise added its inspiration to his feelings, and contributed to render his actions pre-eminently conspicuous even in the high and palmy age of chivalry. He had no sooner ascended the throne than he began to make arrangements for joining the new levies of crusaders preparing to embark for the Holy Land. In such a sphere nature had fitted the king of England to shine without a rival. His landing in Palestine was destined to mark an era, when the Moslemins were to encounter a warrior superior even to the most distinguished of their own in lofty daring and proud contempt of danger, and when the brows of their bravest chieftains were to darken at the name of Richard.

---

[1] Mackintosh's *History of England*, vol. i. p. 172.

At his coronation an event occurred which it is painful to mention, and too shocking to give in detail. The Jews, eager to express their fealty to the new sovereign, approached him in numbers, bearing rich presents of gold and silver, commodities which they well knew would be peculiarly acceptable to the king. In their endeavours to press forward towards the hall door during the state dinner, a scuffle ensued. The Jews resisted the ill treatment they received, which so inflamed the passions of the English mob that they arose upon the defenceless strangers, and drove away or destroyed them. This example of violence spread not only over the city, but throughout the country; and the unfortunate Israelites were massacred and plundered without mercy. It was in vain that the king attempted to allay the tumult; the sanguinary rabble would not desist until its ferocity and rapacity were completely satiated.

Richard having equipped his armament, and acquired the necessary treasure by every means in his power (and from his natural impatience he was never scrupulous upon that point), joined Philip of France and marched with him to Lyons. As the principal events connected with this expedition are already embodied in the article CRUSADES, we shall not recapitulate here the whole details, but only notice such as have not been there introduced. On his way Richard relieved Portugal, by joining the sovereign of that country with five hundred knights, and bidding defiance to the Moors or Saracens. This was an evil omen for the followers of the Prophet. After landing at Messina, he remained there six months, which were chiefly occupied in warm disputes with Tancred, who had usurped the Sicilian crown. On the 10th of April 1191 Richard set sail from this place; but his fleet having been dispersed by a storm, and the ship in which were his sister Joan, and his betrothed wife Berengaria, being driven into Cyprus, he landed on that island for the purpose of chastising the governor, who had treated the royal ladies with some discourtesy. Richard reduced the whole island, and after marrying Berengaria, and causing her to be crowned queen of England, he set sail for St Jean d'Acre, which afterwards surrendered to him. (See ACRE.) The fall of this place opened the way to Jerusalem, towards which he now advanced, performing on his way those chivalrous deeds which taught the infidels to shudder at the apparition of his name. (See CRUSADES.) In October 1192 Richard set sail from the Holy Land for England, with a fleet, which contained his wife and sister, who appear to have reached their destination in safety. But a storm having dispersed the ships, Richard was driven near Marseilles. Having learned, however, that plans were in agitation to seize his person (for Philip of France and other continental sovereigns, together with his brother, were leagued against him), he formed the unfortunate resolution of passing through Germany in disguise.

He landed at Zara, and after a variety of adventures and hairbreadth escapes, he was at last arrested by Leopold, duke of Austria, who immediately ordered him to be loaded with fetters. This prince had served under Richard at the siege of Acre, where he received, or imagined he had received, some injury at his hands, and took this base method of revenging himself. Henry VI. emperor of Germany, was then equally an enemy to Richard, on account of his having married Berengaria, the daughter of Tancred king of Sicily. He therefore required the royal captive to be delivered into his hands, and stipulated to pay a large sum of money to the duke as a reward for his services.

The disaster which had befallen the English monarch could not be long concealed. The news of his captivity spread general indignation at home; a feeling which was responded to by the disinterested portion of Europe. Richard's mother, along with the clergy of Germany, appealed to the pope; and the emperor, finding that his conduct was condemned as disgraceful, made an attempt to justify it, by charging his prisoner with several weighty crimes. These were, his behaviour in Sicily, his conquest of Cyprus, and the alleged murder of Conrad, who was assassinated whilst contending for the Christian kingdom of Palestine. The latter charge being by far the most serious, every effort was made to vindicate Richard from the guilt of the alleged crime. At home the ministry exerted themselves to the utmost; and the most able prelates set out for the Continent to bargain for his ransom. He was removed from a dungeon in the Tyrol to the residence of the emperor at Haguenau, and was taken from thence to Worms, for a final adjustment of differences.

In the meanwhile, his brother John, with Philip of France, were busily prosecuting their plans for his destruction. Their design was to effect the utter ruin of Richard; and every method was tried to accomplish their purpose. John made his feudal submission to Philip for his brother's continental possessions; and having assembled an army, he returned to England with the intention of seizing the crown, whilst his colleague invaded Normandy. Both the confederates were completely unsuccessful. John, by circulating false reports of his brother's death, attempted to give a gloss of right to his projected usurpation; but his duplicity was too well known, and his armament of foreign mercenaries was repulsed from the coast.

The negociations for Richard's liberation ended at last in the agreement that a ransom of one hundred thousand marks of silver should be paid for it. It was in vain that his mortal enemies, Philip and John, protracted his imprisonment. By a general tax the sum was raised; and soon after his emancipation he set out for England, where he arrived on the 13th of March 1194. The remainder of his reign is very unimportant; it was chiefly occupied with a species of petty bickerings with Philip of France. The money required for the crusade, and the ransom of Richard, had so exhausted the finances of England, that the king found himself unable to undertake war upon a grand scale. If we contemplate the character of the individual who found himself thus fettered by pecuniary necessities, this was a fortunate circumstance. It would be difficult to estimate the amount of human misery which was thus saved. After various undecisive battles and equivocal victories, Richard was mortally wounded before Chaluze, an obscure castle in the province of Limousin, held by a rebellious vassal, and expired on the 6th of April 1199, in the forty-second year of his age and the tenth of his reign.

Thus perished, in the prime of life, one of the most romantic characters to be met with in real history.[1] His character we have already given; and with respect to his reign, we cannot discover any thing in which it added to the civilization or prosperity of the country. For the immense sums of money which he drew from it, the only return worthy of notice was an equalization of weights and measures throughout the realm.

---

[1] The lines which Dr Johnson applies to Charles XII. of Sweden are literally true of Richard Cœur-de-Lion of England:

His fate was destined to a foreign strand,
A petty fortress, and a dubious hand;—
He left a name at which the world grows pale,
To point a moral or adorn a tale.

John, the brother of the late king, and the youngest legitimate son of Henry II., succeeded to the throne without opposition; for, although the hereditary right, according to the modern acceptation of the term, was vested in his nephew Arthur, son of John's elder brother Geoffrey, the uncle had likewise a hereditary claim, as being nearest of kin to the deceased monarch, and the nation declared in his favour. His coronation took place on the 27th of May 1199. The character of John is perhaps more strongly marked, and possesses more individuality, than that of any other monarch on the list of English kings. In cowardly villany, in perfidious malignity, in base ingratitude, in unprincipled cruelty, in grossness of appetite, in meanness, weakness, and every vicious infirmity, this prince figures in the page of history almost without a rival. Other kings there may have been whose vices are black enough to call forth the execrations of posterity; but the halo of talent which emblazons their names serves to mitigate the severity of censure. John, however, stands before us utterly divested of any such quality; his character is unredeemed by one solitary virtue; his reign is unillustrated by one solitary good action performed without compulsion. He is altogether alone, the lowest and most abject slave that ever wore a crown.

Richard had destined Arthur as his successor, and, on his death, Maine, Tours, and Anjou, appointed the youth, then Earl of Bretagne, their lord. On the assumption of the crown of England and the dukedom of Normandy by John, Constance, the mother of Arthur, gave her son over to the care of Philip, king of France, who claimed for him his continental possessions. A struggle ensued between the monarchs of France and England. Philip, who, it would appear, used Arthur entirely as a tool to suit his own purposes, sent him with a military retinue into the dominions to which he laid claim. He took the town of Mirabeau, saving a tower, which held out under Eleanor, the widow of Henry II.; but on the night between the 31st of July and 1st of August 1202, John arrived, and compelled the besiegers to surrender. The prisoners were treated with a cruelty truly demoniacal, and worthy of the man; but this was only the opening scene of the tragedy. Prince Arthur was brought to Falaise, where he was confined for some time. He then all of a sudden disappeared, and contemporary history has ascribed to John the guilt of his murder. That the hapless youth met with a violent death is evident, and that he fell either by his uncle's own hands, or by his orders, there seems no reason to doubt. Even in that semi-barbarous age, there was scarcely an individual capable of committing such an atrocity, excepting the wretch who, a few years afterwards, took a diabolical pleasure in starving to death the wife and children of a nobleman who had offended him, and hanging twenty-eight Welsh hostages, besides other atrocities too horrible to be named.

By this foul deed, a third part of John's dominions were wrenched from his grasp. Philip Augustus summoned John, as duke of Normandy and Aquitaine, to answer before a court of peers to the charge of having murdered Arthur duke of Brittany. But he dreaded the tribunal, and having refused to appear, he was branded as a murderer, condemned to death, and adjudged to lose all his French territories. The king of France moved onwards from conquest to conquest, and one by one the provinces of the English monarch were seized and annexed to the dominions of Philip; Touraine, Maine, and Anjou in 1203, the duchy of Normandy in 1205, and the county of Poitou in 1206.

Another important event in the reign of John was his contest with the pope, the only contest indeed in which he ever displayed any thing of that spirit which had fired the bosoms of his ancestors. The clergy had for some time acted as a community independent of the civil power, owning subjection to the pope alone, by whom their elections were usually confirmed. The election of the Archbishop of Canterbury had been a subject of contention between the suffragan bishops of the province, and the monks of St Augustin's Abbey in that city. Each party claimed the right of choosing; but under this question was concealed the more important one, whether the king or the pope had the power of nomination; for the bishops were accessible to the influence of the crown, and the monks, in consistency with the genius of their order, were biassed by Rome. In the mean time the archbishop died, and the monks privately elected Reginald their superior in his room. The bishops remonstrated against this as an innovation on their privileges; and the king took part in the contest, with the resolution of raising the Bishop of Norwich to the primacy. The cause was appealed to Rome; and Pope Innocent III., eager to extend his power in England, commanded the election of Stephen Langton, a most unexceptionable individual, and one who, in the sequel, proved himself eminently worthy of the highest station. John, however, incensed at this proceeding, violently expelled the monks from their convent, took possession of it himself, and seized upon the revenues. The tiara, however, was not to be thus contemptuously treated. An interdict was threatened, unless compliance with the wishes of the papal court was immediately yielded. In vain the prelates in the most suppliant manner entreated the king to give his consent to the measure. With that stupid recklessness of danger which he always uniformly evinced, he [illegible] that [illegible] and the nation should brave the vengeance of Rome. He swore that if it [illegible], he would expel the whole clergy, and confiscate their possessions. The pope, however, laughed his menaces to scorn, and published that terrible interdict, which in those ages was calculated to make the heart of a nation tremble. A stop was immediately put to divine service, and the administration of all the rites of religion, except baptism, and the confession, absolution, and extreme unction to the dying. The church-doors were shut, and the images of the saints deposed. The dead were refused Christian burial, and thrown promiscuously into ditches and on the highways, without any funeral solemnity. Other injunctions, equally severe, were included in this formidable sentence; and John, in revenge, persecuted the clergy with unsparing rigour. But his furious and imprudent efforts proved useless. Innocent remained firm, and, in two years thereafter, 1209, launched his last thunderbolt at the English monarch. He excommunicated John, absolved his subjects from their oath of allegiance, and soon afterwards deposed him. He also commissioned the king of France to take his crown; and published a crusade all over Christendom against King John, exhorting the chivalry of Europe to take up arms against him, and enlist under the French banner. Philip was not less active on his part. He summoned all the vassals of the crown to attend him at Rouen; and having collected a fleet of 1700 vessels, was ready in 1213 to invade England.

But the fulminations of the pope were alike disregarded by John and his subjects, who had now become familiar with them. His strength does not appear to have been lessened, for the only successful expeditions of his reign, those against Ireland and Wales, were undertaken during the period of his proscription by the see of Rome. In order to meet the king of France, he assembled a vast army; but it was not the interest of his holiness to allow matters

History.

At his coronation an event occurred which it is painful to mention, and too shocking to give in detail. The Jews, eager to express their fealty to the new sovereign, approached him in numbers, bearing rich presents of gold and silver commodities which they well knew would be peculiarly acceptable to the king. In their endeavours to press forward towards the hall door during the state dinner, a scuffle ensued. The Jews resented the ill-treatment they received, which so inflamed the passions of the English mob that they soon seized upon the defenceless strangers, and drove away or destroyed them. This example of violence spread not only over the city, but throughout the country; and the unfortunate Israelites were massacred and plundered without mercy. It was in vain that the king attempted to allay the tumult; the sanguinary rabble would not desist until its ferocity and rapacity were completely satisfied.

Richard having equipped his armament, and raised all the money he could, by every means in his power (and from the means to which he resorted he was never scrupulous upon that point), joined Philip of France and marched with him to Vezelay. As the principal events connected with this expedition are already recorded in the article CRUSADES, we shall not recapitulate here the whole details, but only notice such as have not been there introduced. On his way Richard relieved Portugal, by joining the sovereign of that country with five hundred knights, and bidding defiance to the Moors or Saracens. This was an evil omen for the followers of the Prophet. After landing at Messina, he remained there six months, which were chiefly occupied in warm disputes with Tancred, who had usurped the Sicilian crown. On the 10th of April 1191 Richard set sail from this place; but his fleet having been dispersed by a storm, and the ship in which were his sister Joan, and his betrothed wife Berengaria, being driven into Cyprus, he landed on that island for the purpose of chastising the governor, who had treated the royal ladies with some discourtesy. Richard reduced the whole island, and after marrying Berengaria, and causing her to be crowned queen of England, he set sail for St Jean d'Acre, which afterwards surrendered to him. (See ACRE.) The fall of this place opened the way to Jerusalem, towards which he now advanced, performing on his way those chivalrous deeds which taught the infidels to shudder at the apparition of his name. (See CRUSADES.) In October 1192 Richard set sail from the Holy Land for England, with a fleet, which contained his wife and sister, who appear to have reached their destination in safety. But a storm having dispersed the ships, Richard was driven near Marseilles. Having learned, however, that plans were in agitation to seize his person (for Philip of France and other continental sovereigns, together with his brother, were leagued against him), he formed the unfortunate resolution of passing through Germany in disguise.

He landed at Zara, and after a variety of adventures and hairbreadth escapes, he was at last arrested by Leopold, duke of Austria, who immediately ordered him to be loaded with fetters. That prince had served under Richard at the siege of Acre, where he received, or imagined he had received, some injury at his hands, and took this base method of revenging himself. Henry VI. emperor of Germany, was then equally an enemy to Richard, on account of his having married Berengaria, the daughter of Tancred king of Sicily. He therefore required the royal captive to be delivered into his hands, and stipulated to pay a large sum of money to the duke as a reward for his services.

The disaster which had befallen the English monarch could not be long concealed. The news of his captivity spread general indignation at home; a feeling which was responded to by the disinterested portion of Europe. Richard's mother, along with the clergy of Germany, appealed to the pope, and the emperor, finding that his conduct was condemned as disgraceful, made an attempt to justify it, by charging his prisoner with several weighty crimes. These were, his behaviour in Sicily, his conquest of Cyprus, and the alleged murder of Conrad, who was assassinated whilst contending for the Christian kingdom of Palestine. The prisoners were treated with a cruelty truly demoniacal, and worthy of the man; but this was only the opening scene of the tragedy. Prince Arthur was brought to Falaise, where he was confined for some time. He then all of a sudden disappeared, and contemporary history has ascribed to John the guilt of his murder. That the hapless youth met with a violent death is evident, and that he fell either by his uncle's own hands, or by his orders, there seems no reason to doubt. Even in that semi-barbarous age, there was scarcely an individual capable of committing such an atrocity, excepting the wretch who, a few years afterwards, took a diabolical pleasure in starving to death the wife and children of a nobleman who had offended him, and hanging twenty-eight Welsh hostages, besides other atrocities too horrible to be named.

By this foul deed, a third part of John's dominions were wrenched from his grasp. Philip Augustus summoned John, as duke of Normandy and Aquitaine, to answer before a court of peers to the charge of having murdered Arthur duke of Brittany. But he dreaded the tribunal, and having refused to appear, he was branded as a murderer, condemned to death, and adjudged to lose all his French territories. The king of France moved onwards from conquest to conquest, and one by one the provinces of the English monarch were seized and annexed to the dominions of Philip; Touraine, Maine, and Anjou in 1203, the duchy of Normandy in 1205, and the county of Poitou in 1206.

Another important event in the reign of John was his contest with the pope, the only contest indeed in which he ever displayed any thing of that spirit which had fired the bosoms of his ancestors. The clergy had for some time acted as a community independent of the civil power, owning subjection to the pope alone, by whom their elections were usually confirmed. The election of the Archbishop of Canterbury had been a subject of contention between the suffragan bishops of the province, and the monks of St Augustin's Abbey in that city. Each party claimed the right of choosing; but under this question was concealed the more important one, whether the king or the pope had the power of nomination; for the bishops were accessible to the influence of the crown, and the monks, in consistency with the genius of their order, were biassed by Rome. In the mean time the archbishop died, and the monks privately elected Reginald their superior in his room. The bishops remonstrated against this as an innovation on their privileges; and the king took part in the contest, with the resolution of raising the Bishop of Norwich to the primacy. The cause was appealed to Rome; and Pope Innocent III., eager to extend his power in England, commanded the election of Stephen Langton, a most unexceptionable individual, and one who, in the sequel, proved himself eminently worthy of the highest station. John, however, incensed at this proceeding, violently expelled the monks from their convent, took possession of it himself, and seized upon the revenues. The tiara, however, was not to be thus contemptuously treated. An interdict was threatened, unless compliance with the wishes of the papal court was immediately yielded. In vain the prelates in the most supplicating manner entreated the king to give his consent to the measure. With that stoical indifference to human suffering which he uniformly evinced, he determined that both himself and the nation should brave the vengeance of Rome. He swore that if it descended upon him, he would banish the whole clergy, and confiscate their possessions. The pope, however, laughed his menaces to scorn, and published that terrible interdict, which in those ages was calculated to make the heart of a nation tremble. A stop was immediately put to divine service, and the administration of all the rites of religion except baptism, and the confession, absolution, and extreme unction to the dying. The church-doors were shut, and the images of the saints deposed. The dead were refused Christian burial, and thrown promiscuously into ditches and on the highways, without any funeral solemnity. Other injunctions, equally severe, were included in this formidable interdict; and John, in revenge, persecuted the clergy with unsparing rigour. But his furious and imprudent efforts proved useless. Innocent remained firm, and, in two years thereafter, 1209, launched his last thunderbolt at the English monarch. He excommunicated John, absolved his subjects from their oath of allegiance, and soon afterwards deposed him. He also commissioned the king of France to take his crown; and published a crusade all over Christendom against King John, exhorting the chivalry of Europe to take up arms against him, and enlist under the French banner. Philip was not less active on his part. He summoned all the vassals of the crown to attend him at Rouen; and having collected a fleet of 1700 vessels, was ready in 1213 to invade England.

But the fulminations of the pope were alike disregarded by John and his subjects, who had now become familiar with them. His strength does not appear to have been lessened, for the only successful expeditions of his reign, those against Ireland and Wales, were undertaken during the period of his proscription by the see of Rome. In order to meet the king of France, he assembled a vast army; but it was not the interest of his holiness to allow matters to be carried to extremities. He accordingly sent over two legates, Pandulf and Durand, who, in a meeting of parliament holden at Northampton, ventured to declare to John that he was bound to obey the holy see as much in temporal as in spiritual affairs. After shuffling, according to custom, John, at the head of an army capable of bidding defiance to any invader, surrendered himself to the will of the pope, and acceded to all the terms which Pandulf had exacted. With a meanness of spirit almost exceeding belief, he laid his crown at the feet of the haughty legate, resigned England and Ireland into the hands of the pope, swore homage to him as his liege lord, and took an oath of fealty to his successors. The terms of this remarkable oath deserve a place in every history.

" I John, by the grace of God king of England and lord of Ireland, in order to expiate my sins, from my own free will and the advice of my barons, *give* to the church of Rome, to Pope Innocent and his successors, the kingdom of England, and all other prerogatives of my crown. I will hereafter hold them as the pope's vassal. I will be faithful to God, to the church of Rome, to the pope *my master*, and to his successors legitimately elected. I promise to pay him a tribute of 1000 merks ; to wit, 700 for the kingdom of England, and 300 for the kingdom of Ireland." This memorable submission took place on the 15th of May 1213.

This oath was taken by the king before all the people, kneeling, and with his hands held up between those of the legate. Having then agreed to install Langton in the primacy, he received the crown which he had been supposed to have forfeited; whilst the legate, to add to his former insolence, trampled under his feet the tribute which John had consented to pay, but afterwards stooped to gather it up. The king of France was enraged at this behaviour of the pope, and resolved to execute his project of conquering England in spite of him and his censures. His fleet, however, was attacked in their harbours by the English, who took three hundred vessels, and destroyed about a hundred more; whilst Philip, finding it impossible to prevent the rest from falling into the hands of the enemy, set fire to them himself, and thus abandoned the enterprise. This naval action is memorable as being the first which took place between the fleets of France and England, and was a good omen for the latter.

John being thus delivered from all danger, continued to follow the same cruel and tyrannical measures which had hitherto rendered him odious to his subjects. His scandalous subjection to the clergy now gave the barons an opportunity of exerting themselves, in order to reduce the enormous prerogatives of the crown. Their designs were greatly facilitated by the concurrence of Langton the primate, who on all occasions showed a sincere regard for the interests of the kingdom. At a synod of his prelates and clergy, convened in St Paul's on pretence of examining into the losses of some bishops who had been exiled by John, he privately conferred with a number of barons, to whom he expatiated upon the vices and injustice of their sovereign. He showed them a copy of Henry I.'s charter, the only one in the kingdom, having been found amidst the rubbish of an obscure monastery. Langton exhorted the barons to insist on a renewal thereof; and this they solemnly swore to perform. The same agreement was afterwards renewed at a more numerous meeting of barons summoned by Langton at St Edmondsbury. Here it was resolved that at Christmas they should prefer their common petition in a body, and in the mean time they separated, intending to put themselves in a posture of defence, to enlist men, and to make other warlike preparations. In the beginning of January 1215 they repaired to London, accoutred in the military garb and with their equipage, and presented their petition to the king, alleging that he had promised to grant a confirmation of the laws of Edward the Confessor, at the time when he was absolved from his excommunication. John resented their presumption ; and required a promise under their hands and seals that they would never demand or attempt to extort such privileges in future. But this they refused with such unanimity and resolution, that the king desired time to consider of their petition ; at the same time promising that, at the festival of Easter, he would give a positive answer. He also offered securities, which the barons accepted, and thereafter withdrew.

John, however, had no intention of complying with their demands, for it is evident that his promise was extorted from him by fear. He had recourse to the clergy, whose favour he propitiated by promising many things which he had not the slightest intention of ever performing. The pope was likewise appealed to, who threw the weight of his authority into the scale of his vassal, and exhorted the barons to abandon their treasonable enterprise. At the same time his holiness also agreed to consider their petition, and to endeavour to obtain for them the concession of those demands which appeared to be just. But, happily for English liberty, the confederates disregarded the injunctions of Innocent III., who by his decision had now more embroiled the fray. Both parties gave up all hopes of a peaceful negociation at the ensuing festival, and made the best preparations they could for war, in which the barons had an unequivocal superiority.

After waiting until Easter, when the king promised to return them an answer, they met by agreement at Stamford. There they assembled a force of above two thousand knights, with a prodigious number of foot, and thence marched to Brackley, about fifteen miles from Oxford, then the court residence. John, hearing of their approach, sent the Archbishop of Canterbury, the Earl of Pembroke, and others of his council, to know the particulars of their request, and what those liberties were which they so much importuned him to grant. The barons delivered a schedule containing the chief articles of their demands, founded on the charters of Henry and Edward, but which were in the highest degree displeasing to the king. He burst into a furious passion, and, asking the barons why they did not also demand his kingdom, swore that he would never comply with such exorbitant requests. The confederates then as their general chose Robert Fitzwalter, whom they dignified with the title of Mareschal of the army of God and of the holy church. They laid siege to Northampton, but were repulsed ; they, however, took Bedford, and were joyfully received into London.

The concurrence of the metropolis proved decisive of the contest. It was in vain that the pope fulminated a bull in favour of his vassal John ; the many were unanimous, and the few were compelled to yield the point. The king, with a court now reduced to seven attendants, retired to Odiham, where, seeing the necessity of submitting, he agreed to a friendly conference. The barons named, as a proper place for meeting, Runnymede. It was a meadow situated between Staines and Windsor, and, like the holy ground of the Hebrews, it is still held in veneration as the spot where the standard of English freedom was first unfurled. On the 15th of June 1215, both parties met there ; and having taken up separate stations, a long discussion ensued, which terminated in the king signing the charter, called, by way of pre-eminence, Magna Charta. For a particular account of the great charter, which for centuries afterwards was looked upon as the palladium of our national freedom, the reader is referred to the article MAGNA CHARTA.

This charter, however, at the time when it was granted, secured liberty to the clergy, the barons, and the gentlemen, much more than to the bulk of the people, who did not for a long time obtain any privileges of importance. Freedom of elections was secured to the clergy; and it was determined that fines imposed on them for any offence should be laid on in proportion to their estates, and not the value of their benefices. The privileges secured to the barons were, either abatements in the rigour of the feudal laws, or relief from arbitrary and ambiguous decisions before the courts. It was also decreed that barons should recover the lands of their vassals, even though forfeited by felony, after having been in the possession of the crown for a year and a day; and no tax was to be imposed without consent of the great council of the nation, excepting in case of the captivity of the king, the knighting of his eldest son, or the marriage of his eldest daughter. No land belonging to any baron was to be seized for a crown debt, except when the possessor had not personal property enough to pay it; neither was any vassal to be allowed to sell so much of his land as to incapacitate him from performing the necessary service to his lord. It was also determined, that when the great council of the nation was called, the prelates, earls, and barons should be summoned by a particular writ, and that the lesser barons should receive a summons from the sheriff. In favour of the people it was stipulated, that they should receive from the barons all the immunities and privileges granted by the king to the former. Merchants were to be allowed to carry on their business without any arbitrary tolls or impositions, and to go out of the kingdom and return at pleasure. The goods of every freeman were to be disposed of according to his will; or if he died intestate, the nearest heir was in that case to succeed him. No carts, horses, or wood were to be taken by the crown officers without the consent of the owner. The king's courts were to be stationary; no delay was to take place in doing justice to every one; and no freeman was to be taken or imprisoned, dispossessed of his free tenement, outlawed, or banished, unless by the legal judgment of his peers. It was likewise stipulated that London should remain in the hands of the barons, and that the Tower should be consigned to the primate, till the 15th of August following, or till the articles contained in the charter were fulfilled. In order to secure the accomplishment of this, the king allowed them to choose twenty-five of their own number, to whose authority no limits were assigned. If any complaint were made of a violation of the charter, either by the king or his officers, any four of the barons might admonish the king to redress the grievance; and if satisfaction were not obtained, they might assemble the whole council of twenty-five and, in conjunction with the great council, compel him to fulfil the charter. In case of his resistance, they had liberty to levy war against him, attack his castles, and use every kind of violence, except against his person, or those of his queen or children. All men throughout the kingdom were bound, under the penalty of confiscation, to swear obedience to the twenty-five barons; and the freeholders of each county were to choose twelve knights, whose business it was to report such obnoxious customs as ought to be redressed in terms of Magna Charta.

But although John had thus been obliged to recognise the liberty of his subjects, he had no mind that they should in reality enjoy it. The sense of his subjection to his own vassals sunk deep into his soul, and he became sullen, silent, and reserved. He shunned the society of his former friends, and retired into the Isle of Wight, as if to hide his disgrace in solitude, but, in reality, to meditate plans of revenge. He sent to the Continent in order to enlist a large body of mercenary troops, and made heavy complaints to the pope on account of the insurrections of the barons against him. The pontiff, as might be expected, warmly espoused his cause; a bull was sent over annulling the whole charter; the principal barons were excommunicated by name, and declared to be worse than Saracens; and at the same time the foreign troops arriving, the king once more found himself in a condition to demand his own terms from his untractable subjects.

The barons had made no preparations for war, not suspecting the introduction of a foreign army. The king, therefore, was for some time undisputed master of the field, and the most horrid cruelties were committed by his army. The nobility who had been most active in procuring the great charter accordingly fled with their families to Scotland, where they obtained the protection of King Alexander by doing homage to him. The barons, finding themselves totally unable to raise an army capable of contending with that of John, resorted to the equivocal and perilous expedient of calling in foreign aid. They applied to their old enemy Philip of France, offering the crown to his eldest son Louis, upon the condition of their being protected from the fury of John, and the unprincipled mercenaries whom he commanded. The French king eagerly accepted their proposals, and dispatched his son with a powerful army to England. He was received by the barons with great acclamations, and having united their forces, they secured all the southern counties. Essex and Sussex were soon after added; and they advanced successfully into Norfolk, spreading around them all the devastations of civil war. The forces of John occupied the northern districts, where the king of Scotland harassed him by an invasion of Northumberland. But these hostilities, which might ultimately have ruined the independence of the country, by sinking it to the level of a French province, were happily terminated by the death of John, in the forty-ninth year of his age, and seventeenth of his reign. His demise took place at Newark, on the 19th of October 1216. The death of this monarch was as much a public blessing as his reign had been a national misfortune. The signing of Magna Charta is the only event of his life which is worthy of being recorded in history. He, however, deserves no credit for that act, which was the result of compulsion. As well might we consider honesty the actuating principle or motive of the malefactor who consents to deliver up the treasure of which he had possessed himself, when he comes in sight of the wheel upon which, in case of refusal, he is to be broken alive.

John left six legitimate children, namely, three sons and three daughters. The eldest of the former, Henry of Winchester, was only ten years of age when he found himself in possession of the title, although not entirely of the power, of king. He was crowned as Henry III. upon the 28th of October 1216, nine days after he succeeded to the inchoate right to the throne. The care of his person was entrusted to the Earl of Pembroke, earl-marshal, with the style and title of guardian of the kingdom. Through the instrumentality of this nobleman the great charter of liberties was revived, and the claims of the crown were reconciled with those of the subject, to the satisfaction of the adverse barons. Besides the eldest son of John, there was another competitor for the crown, namely, Louis of France, who had been called over by the barons of Runnymede, in order to take possession of the English throne. For some time Louis kept the field, and not without success; but he was defeated at Lincoln; and a fleet which his father had sent to him with succours having been totally destroyed by the English, he was compelled to abandon the enterprise, and to make an honourable retreat.

A peaceful king is looked upon either as imbecile or as pusillanimous by an age which feels the intoxication of military glory, and considers the principal duties of a monarch to be "to go out and in before his people, and fight their battles." The reign of Henry III. is but little adorned with the triumphs of war; and, if we are not mistaken, it has been too much depreciated on this account. But this fact, as well as his monarchical character, we will be enabled to ascertain with more certainty after we have passed in review the principal events of his reign. Its early history exhibits only some of those evils incident to an injudicious, but not, strictly speaking, wicked administration. In 1225 the great charter was a third time confirmed, upon the occasion of Henry assembling a great council, and urgently demanding aid against a pretended invasion of the French. In consequence of this, it has ever since retained its place at the head of English statutes. The wardship of the young king had now solely devolved upon Hubert de Burgh, the grand justiciary, and a man of ability and spirit, but nurtured under Richard and John. For several years he ruled as the favourite without control, repressing the disorders of the times with a vigorous, but, in the eye of an enlightened age, cruel policy. In 1227, Henry was declared in parliament to have attained to the years of discretion; and two years afterwards he resumed the project of conquering France, and landed there with a considerable army. The expedition proved most disgraceful to the English arms; and in a year after he returned to his country not a little humbled in its estimation, as well as his own. The next event of importance which we meet with is the disgrace of De Burgh, who was accused of negligence and treachery in the discharge of his duties; with what degree of truth it is difficult now to determine. He was imprisoned for some time, but afterwards restored to liberty, honours, and emoluments.

In 1236, Henry espoused Eleanor of Provence. This event gave rise to a new immigration of foreigners of higher rank and more specious pretensions than those who usually flocked to the soil of England. One of the queen's uncles became prime minister, a second was made primate, and a third Earl of Richmond. This favouritism excited much discontent both amongst the native barons and the people. The other events of this long reign consist of petty wars and bickerings with France, Scotland, and Wales. The prodigality of the king was extreme, and he was repeatedly compelled to lay his necessities before parliament and solicit supplies. These were as often afforded; but notwithstanding these grants, he had frequent recourse, under specious pretexts, to the most unjust exactions. Meanwhile England rapidly increased in wealth, and widely extended her commercial relations with other countries.

In the year 1254, at the instance of the pope, Henry accepted of the crown of Sicily for his son Edmund. It had been formerly offered to his brother Richard, who was wise enough not to accept of it, probably because he felt himself unable to compete with the other powerful princes who aspired to it. In order to raise the money necessary to carry his foolish project into execution, Henry had recourse to every expedient which the regal or papal ministers could devise. The principal burden fell upon the clergy, who, by the menace of excommunication on the one side, and of forfeiture on the other, were compelled to submit. This oppression widened more and more the breach between the king and his people; and he found it necessary at last to look to the security of his own crown, instead of fighting for a foreign diadem to grace the brow of his son.

Amongst the foreigners of distinction who established themselves in England during the reign of Henry III. was Simon de Montfort, earl of Leicester. He was the younger son of the Count de Montfort, celebrated in the annals of religious warfare for his cruel crusade against those dissenters from the Roman faith called Albigois or Albigenses. Simon the younger received the hand of King Henry's sister in marriage, and very early began to act a conspicuous part in the civil commotions which agitated the country. He was a bold and ambitious man; and placing himself at the head of the disaffected barons, he formed a powerful confederacy against the king. In the year 1258, a famous parliament was summoned at Oxford, in order to digest the new plan of government, and to elect to the chief authority such individuals as were deemed worthy of trust. This assembly, afterwards celebrated in our annals by the derisive name of the *mad parliament*, went very expeditiously to work in the business of reformation. Twenty-four barons were appointed, with supreme authority, in order to reform the abuses of the state; and Leicester was placed at their head. Twelve of these barons were chosen by the king's council, and twelve by the parliament. Their first step was to order four knights to be chosen out of each county, who should examine into the state of their respective constituents, and attend at the ensuing parliament to give information of their complaints. They ordained that three sessions of parliament should be regularly held every year; that a new high sheriff should be elected annually; that no wards nor castles should be entrusted to foreigners, no new forests made, nor the revenues of any counties farmed out. Thus far these provisions were good, and an approximation to popular representation, although some modern writers have designated the whole transaction as a revolution.

The twenty-four barons continued to conduct the affairs of government for several years; but they at last began to quarrel amongst themselves. The Earls of Gloucester and Leicester pursued opposite interests, and formed opposite parties, who eyed each other with mutual jealousy. Leicester, perceiving that his rival was likely to gain the ascendency, retired to France; but the balance was again restored in his favour by the union of Prince Edward with his friends. A short time after this event, the rival parties seem to have assumed, if not the reality, at least the appearance of unanimity. In 1262, Henry made a fruitless attempt to escape from the authority of the barons; but his son Edward remained firm to their cause, on account of his having sworn to observe the provisions of Oxford. After other ineffectual attempts upon the part of the king, he agreed that the twenty-four noblemen should continue to govern, not only during his own reign, but also during that of his successor. By this stipulation, Edward joined his father, which restored vigour to the royalists, and more equally balanced the power of the parties. It was proposed that the differences between them should be submitted for arbitration to Louis IX., and both swore to abide by his decision. That excellent monarch enjoined the restoration of all castles, possessions, and royal rights enjoyed by the crown before the parliament of Oxford, upon condition of universal amnesty, and of the full enjoyment of all the privileges and liberties granted by the charter. The award was confirmed by the pope, who empowered the Archbishop of Canterbury to excommunicate all who refused to submit to it.

The moment the decision was made known to the barons, they declared it to be contrary to truth and justice, and immediately took the field. The contest was at first favourable to the royal prerogative; but in 1264 Prince Edward lost a great battle by his impetuosity in pursuing too far one of the wings of the enemy's army, which he had defeated. His father and uncle were taken prisoners, and placed in the castle of Lewis, where he contrived to join them. They acceded to the propositions submitted to them, and the administration of the kingdom fell into the hands of the Earls of Gloucester and Leicester, and the Bishop of Chichester.

The situation to which the kingdom was now reduced proved at last the means of settling the government upon a more proper foundation. Leicester, in order to secure himself, was obliged to have recourse to an aid, till now entirely unknown in England, namely, that of the body of the people. He called a parliament, where, besides the barons of his own party, and several ecclesiastics who were not properly tenants of the crown, he ordered returns to be made of two knights from every shire; and also deputies from the boroughs, which had been hitherto considered as too inconsiderable to be allowed any share in the legislation. This parliament was called on the 22d of January 1265; and here we find the first outline of an English House of Commons; an institution which has ever since been considered, and justly, as the bulwark of British liberty.

The new parliament was far from being so compliant to Leicester as he had desired or expected. Many of the barons who had hitherto stedfastly adhered to his party were disgusted with his boundless ambition; and the people, who found that a change of masters was not a change of circumstances, began to wish for the re-establishment of royal authority. Leicester at last, making a virtue of necessity, released Prince Edward from his confinement, and had him introduced at Westminster-hall, where his freedom was confirmed by the unanimous voice of the barons. But though Leicester had all the popularity of restoring the prince, he was yet politic enough to keep a strict watch over him. Edward was nominally free, but in reality a prisoner. At last, however, he found means to effect his escape. The Duke of Gloucester, being disgusted with Leicester, left the court, and retired to his estates upon the borders of Wales. His antagonist pursued him thither, and, in order to give the greater authority to his arms, carried the king and Prince Edward along with him. This afforded young Edward an opportunity which he had long desired of making his escape. Being furnished by the Earl of Gloucester with a horse of extraordinary speed, he took leave of his attendants, or rather his guards, under pretence of trying the mettle of his steed. He was hotly followed; but an end was put to the pursuit by the appearance of some of Gloucester's troops.

No sooner was the prince at liberty than the royalists joined him from all quarters, and an army was soon assembled which proved more than sufficient to meet the forces of Leicester. The latter now found himself in a remote quarter of the kingdom, surrounded by his enemies, and shut out from all communication with his friends by the river Severn, the bridges on which Edward had broken down. In this extremity he wrote to his son to hasten to his assistance from London, with a considerable body of troops which the latter had under his command. With this view his son advanced to Kenilworth; but here he was surprised by Prince Edward, and the greater portion of his followers were made prisoners. The young prince immediately advanced upon Leicester himself, whose last anchor had given way with the defeat of his son. He was by no means able to cope with the royalists; his men were inferior both in numbers and resolution to their antagonists. In the battle which ensued, the royalists gained a signal victory over their opponents, defeating them with great slaughter. Leicester himself was slain, together with his eldest son Henry, and about a hundred and sixty knights and other gentlemen. The body of the fallen earl was mutilated in a frightful manner, and portions of it sent to various places. His memory was long revered by the people, who looked upon him as a martyr to the liberties of the realm. But a vigorous reign ensued, and the national feeling was suppressed, or directed to other objects. He left, however, an imperishable name, as the first who had called together a parliament of which the lower house composed part.

The victory of Evesham restored the fortunes of the royalists. The followers of Leicester were proscribed, and their lands distributed amongst the victors. With the death of Montfort the spirit departed from the baronial party, whose members hastened to give in their submission, and to open the gates of their castles to the king. Several places, however, still held out; but by the activity and valour of Prince Edward they were all finally reduced. The country submitted, and the royal authority was completely re-established throughout the realm. The good sense of Edward, however, infused a wiser and more popular spirit into the conduct of government. So judicious appears to have been his administration, indeed, that, in a few years after the battle of Evesham, he felt himself in a capacity to take the cross, and enlist under the banners of the crusaders. This step of the heir apparent to the crown of England may appear somewhat extraordinary, when we consider the advanced period of life to which his father had now attained, and the civil commotions from which he had so recently emerged. But in an age when it was common to ascribe any sudden transition of fortune from one extreme to another, to the immediate interposition of providence, it is less to be wondered at. The recent deliverance of himself and his father from their enemies had incurred a debt of gratitude to heaven which it was now his desire to pay off. His expedition to the Holy Land was of little importance, and was moreover in no way connected with the history of his country, although it was distinguished by those romantic adventures and chivalrous feats of arms peculiar to the age, and more especially to the wars in Palestine.

The remaining events of Henry III.'s reign afford no materials for history. He died on the 16th of November 1272, in the fifty-seventh year of his reign. The character of Henry is not strongly marked either by good or by evil. During its long continuance we see no premeditated crime, no deep laid plot involving the liberties of his subjects, with which to impeach his memory. The evils which grew and prospered whilst he held the sceptre did not arise from vices in the sovereign, but from the unsettled state of society and the turbulent spirit of the times. His virtues, however, were not very conspicuous; they were rather of a passive than of an active kind; rather the negative of vice than positive moral greatness. With regard to intellect, he appears to have been below mediocrity; and it is usual with historians to describe him as deficient in capacity to govern. This was probably the case, but it was productive of inconvenience to himself rather than misery to his subjects. Under his pacific rule, as we have already observed, the nation grew more rapidly in wealth and prosperity than it did under the more dazzling sway of his military progenitors.

Edward, upon hearing the news of his father's death, and feeling himself secure of the throne, returned slowly from the Holy Land. He arrived in England in August 1274, and was crowned at Westminster on the 19th of the same month. Two years afterwards he undertook an expedition against Lewellyn, prince of Wales, who had refused to do homage for his crown. The conquest of that country cost him some trouble, and was not completed until the year 1283. After this period the principality of Wales was annexed to the crown of England, and thenceforth conferred a title upon the king's eldest son. In 1286, Wales had been so entirely broken into subjection, that Edward undertook a journey to the Continent for the purpose of mediating a peace between Alonzo of Aragon and Philip the Fair of France. These two monarchs had differed about the kingdom of Sicily; but a negociation was effected, and the king of England returned to his country after an absence of three years, during which period much disorder had been introduced into his dominions. Robbery and violence had become frightfully prevalent, and the corruption of the judges had poisoned the fountains of justice. In order to remedy these evils, Edward summoned a parliament, and cited the delinquents to appear and take their trial. All of them, except two clergymen, having been convicted of flagrant acts of corruption and bribery, were accordingly fined, and deposed from their office.

The next great event of Edward's reign was an attempt to subjugate Scotland. This he never altogether effected, although he succeeded in reducing the country to great distress, and in even nominally attaching it to the English crown as a conquered province. For an account of these transactions, see the article SCOTLAND. Edward was at the same time engaged in expensive contests with France; and these multiplied wars, by obliging him to have frequent recourse to parliamentary supplies, became the remote causes of great and important changes in the government. The parliament was modelled into the form which it has ever since retained. As a great part of the property of the kingdom, by the introduction of commerce and by improvements in agriculture, was transferred from the barons to the lower classes of the people, so their consent was thought necessary in order to raise the supplies. For this reason the king issued writs to the sheriffs, enjoining them to send to parliament, along with two knights of the shire, two deputies from each borough within their county; and these, too, provided with sufficient powers from their constituents to grant such demands as they should think reasonable for the safety of the state. The charges of these deputies were to be borne by the boroughs which sent them; and so far were they from considering this deputation as an honour, that nothing could be more displeasing to any borough than to be thus obliged to send a deputy, or to any individual than to be thus chosen. The authority of these commoners, however, increased in course of time. Their union gave them weight; and it became customary among them, in return for the supplies which they granted, to prefer petitions to the crown for the redress of grievances. The more the king's necessities increased, the more he found it necessary to give them an early hearing, until, from requesting, the commons proceeded to demanding; and having all the property of the nation, they by degrees began also to be possessed of a considerable share of the power.

Edward I. died of a dysentery, near Carlisle, on the 7th of July 1307, as he was leading a great army into Scotland, against the inhabitants of which he had vowed the most dreadful vengeance. Edward ranks amongst the greatest monarchs of England. In military talents, in sound judgment, in vigour, decision, irascibility, and vindictiveness, he bore some resemblance to the Conqueror. Like him too he possessed an unsatiable ambition, and his unholy crusade against the independence of Scotland must be regarded as an indelible blot upon his memory. He was succeeded by the eldest of his surviving sons, who bore his father's name, but inherited nothing of his capacity, and who was crowned on the 8th of July 1307, with great magnificence. His father had charged him upon his death-bed to prosecute the war against Scotland until he had finally subdued the kingdom; but war had few attractions for Edward II., and he withdrew his army ingloriously from the country which his father went to subjugate. The first years of Edward's reign are distinguished for nothing but bickerings with his barons, who finally extorted from him a reformation of abuses in full parliament. The Scots in the mean time gradually recovered their power; and Edward having invaded their country with a prodigious force, was met by Robert Bruce at Bannockburn, near Stirling, who totally defeated the puissant army of the English on the 24th of June 1314. See SCOTLAND.

The reign of Edward II. was one continued series of quarrels with his turbulent subjects. His favourites were the most general causes of discontent. The first of these was one Pierce Gaveston, the son of a Gascon knight of some distinction. The latter had honourably served the late king, and, in reward for his services, had obtained an establishment for his son in the family of the Prince of Wales. To be the favourite of any king whatsoever is no doubt in itself a sufficient offence to the rest of the courtiers. Numberless faults were therefore found with Gaveston by the English barons. When the king went over to France to espouse the Princess Isabella, to whom he had been long contracted, Gaveston was left guardian of the realm, with more ample powers than had usually been conferred in such cases. But upon the arrival of the queen, who was of an imperious and intriguing spirit, Gaveston had the misfortune to fall under her displeasure, on account of the ascendency he had acquired over the king. A conspiracy was soon formed against the favourite, at the head of which was the queen and the Earl of Lancaster, a relation of the king's, and the most powerful nobleman in England. Edward found himself unable to protect his favourite against such a formidable combination, and was compelled to banish him. His recall some time afterwards again spread alarm over the country, and kindled a civil war. The nobility were successful in obtaining possession of the obnoxious Gaveston; and, in order to free themselves for ever from uneasiness on his account, they put him to death.

After the defeat of Bannockburn, King Edward chose a new favourite named Hugh le Despencer. He was a young man of a noble English family, and possessed some merit, and engaging accomplishments. His father was a person of apparently unimpeachable character, but he also enjoyed the king's favour, and that was a sufficient crime. The king imprudently dispossessed some lords of their estates, in order to bestow them upon young Despencer. This afforded a sufficient pretext to the barons for openly attacking both the father and son. The Earls of Lancaster and Mortimer, chief of the Welsh marshes, flew to arms; and sentence of perpetual exile against the two Spencers, with a forfeiture of all their estates, was procured from parliament. At last the king took the field, and obtained a signal victory over the other party at Boroughbridge. The Earl of Lancaster was made prisoner, and beheaded a few days afterwards at his own castle of Pomfret. This individual was canonized in 1389. Many other noblemen suffered the same punishment without having the same respect paid to their memory, whilst Mortimer was condemned to perpetual imprisonment.

The triumph of the Spencers was now complete; but the partiality with which the king regarded his two favourites had the effect of alienating not only the affections of his subjects, but also those of his queen. Other charges are brought against Edward as having contributed to effect this estrangement, and Isabella sought an opportunity of escaping from her husband. The palace of her brother at Paris was her natural place of refuge. A rupture having commenced between England and France, the queen proceeded to the court of the latter as negociator, and concluded a peace humiliating to her husband. But she had another object in view in visiting her native country. Her residence became a sanctuary for the English malcontents, who flocked to her in great numbers; and amongst these came Mortimer, who had contrived to effect his escape, and for whom she has been charged with entertaining a stronger passion than that of friendship. The cause of quarrel between the two powers was the county of Guienne, for which the monarch of France required Edward to do homage and fealty. The disputed territory was resigned to the young Prince of Wales, who joined his mother, and made the necessary submissions. When Isabella considered that matters were sufficiently matured for executing her purpose, she landed in England on the 22d of September 1326, where she was universally welcomed, and immediately joined by the most potent barons. The unfortunate king found that the spirit of disloyalty had spread over the whole kingdom. Some dependence was placed upon the garrison of Bristol, which was commanded by the elder Spencer; but the soldiers rebelled against their governor, and delivered him into the hands of the barons, by whom he was cruelly put to death. Young Spencer did not long survive his father. Along with some others who had followed the fortunes of the wretched king, he was made prisoner in an obscure convent in Wales; and the queen having no patience to wait the formality of a trial, gave orders for his immediate execution.

In the mean time the king was discovered and delivered up to his adversaries, who loaded him with insults. He was conducted to the capital, and consigned to the Tower. The charge against him exhibited no other crimes than his incapacity to govern, his indolence, his love of pleasure, and his accessibility to evil counsel. His deposition was quickly voted by parliament; he was assigned a pension for his support; his son Edward, a youth of fourteen, was appointed to succeed him, and the queen was nominated regent during the minority. But the deposed monarch did not long survive his disgrace. He was at first put into the custody of the Earl of Lancaster; but this nobleman having shown some marks of respect and pity for the misfortunes of his sovereign, the latter was taken out of his hands and delivered over to the Lords Berkeley, Maltravers, and Gournay, who were entrusted alternately, each for a month, with the charge of guarding him. Whilst he was in Berkeley's custody, he was still treated with some degree of humanity; but when the turn of Maltravers and Gournay came, every species of indignity was practised upon him, as if they had designed to accelerate his death by accumulating his mental sufferings. As his persecutors, however, saw that his death might not speedily arrive, even under every cruelty which ingenuity could devise, and as they were daily afraid of a revolution in his favour, they determined to put their fears to rest by destroying him at once. Mortimer, therefore, secretly gave orders to the two keepers to dispatch the king; and these ruffians contrived to render the manner of his death as barbarous as possible. Taking advantage of Berkeley's sickness, in whose custody he then was, and who was thereby incapacitated from attending to his charge, they came to Berkeley Castle, and obtained possession of the king's person. They threw him on a bed, and held him down with a table which they had placed over him. They then ran a horn pipe into his bowels, through which they conveyed a red-hot iron; and thus deprived him of life without disfiguring his body. The murderers fled on the perpetration of this horrible enormity; for the dying agonies of the king created suspicions which ended in the discovery of the crime. One of the fugitives was taken at Marseilles, and beheaded on his way to England. The other concealed himself for some years in Germany; but having found means of rendering some services to Edward III. he ventured to approach the person of that monarch, and by his humiliating submission received a pardon.

By the death of Edward II. the government fell entirely into the hands of the queen and Mortimer, who had now the disgraceful pre-eminence of royal paramour. The parliament, which had raised young Edward to the throne, had indeed appointed twelve persons as his privy council, to direct the operations of government. Mortimer excluded himself, under a show of moderation; but at the same time secretly influenced all the measures which came under their deliberation. As this influence began very soon to be perceived, and the queen's criminal attachment to Mortimer was universally known, the administration soon became obnoxious to the people. It had continued four years, when a circumstance occurred which added greatly to its unpopularity. The Scots having made an irruption into England, were met by an overwhelming force under young Edward, or rather Mortimer. The results of this mighty expedition were most ludicrous. By their superior skill and activity, the Scots foiled the English commanders, and made their escape into their own country. Soon after this inglorious campaign, a solemn treaty of peace was concluded, in which Edward, for a sum of money, renounced every claim of superiority over Scotland. This, although a commendable act of moderation, was not calculated to propitiate the favour of the English people. It was not long before another stroke of Mortimer's power and policy startled the nation from its propriety, and paved the way for his own destruction. Amongst those who began to betray indignation against the encroaching spirit of Mortimer, was Edmund earl of Kent, who, deceived into a belief that his brother Edward II. was still alive, wrote a letter to that prince, which was betrayed into the hands of Mortimer, now Earl of March, by the individual who had undertaken to deliver it. The writer of the epistle was immediately tried for high treason, condemned, and executed. There is little doubt that the whole affair of the letter was a plot laid for the destruction of Kent, not only to get him out of the way, but to show that there was no one too high not to be struck down by the vengeance of Mortimer.

Edward finding the restraint under which he was retained becoming irksome, resolved to shake it off, and to rid himself and the nation at once of an authority which had now become alike odious to both. The queen and her paramour had repaired to Nottingham, where a parliament was then held. They had chosen the castle as a place of residence, and taken every precaution to ensure their safety; for fear follows guilt like its shadow. The enemies of Mortimer, however, found means to obtain admission at dead of night; and having seized him as he lay in an apartment adjoining to that of the queen, he was taken prisoner to London, tried before his peers for various crimes, convicted, and executed.

The queen, who was perhaps the most culpable of the two, was screened from capital punishment by the dignity of her station, but stripped of all power, and confined for life to the castle of Risings. From this imprisonment she was never liberated, but during her life the king paid her an annual visit of ceremony.

Edward III. proved one of the greatest warriors who had ever sat on the English throne. His first attempts were to raise Edward Baliol to the throne of Scotland: this however he failed in effecting. But his mind now began to be diverted to loftier and more ambitious speculations. The crown of France became the object of contest between Edward, the son of Philip the Fair's daughter Isabella, and Philip of Valois, the son of the brother of Philip. The question was, whether the crown was descendible only through males, or whether it might be claimed by the nearest male although his descent was by females. Charles the Fair died in 1328, and left the crown of France without direct male descendants to inherit it. The three last kings were the sons of Philip the Fair, and they all reigned successively, but died without issue. According to the English law, the son of the daughter precedes the nephew in inheritance; but the French Salic law excluded females. Edward contended that the feudal laws of France forbade females to inherit who could not perform the feudal duties, yet that their male heirs were not debarred by the spirit of this law, because they were competent to discharge all the military services required. On the other hand, it was insisted by the French advocates for Philip de Valois, that the exclusion of the female in the first instance was an exclusion of all the descendants of either sex. If it had been a question of succession to the English crown, it would have been rightfully determined by the parliament and law of England; but as it concerned the crown and law of France, it was clearly a matter for the French state and lawyers to decide. They decided in favour of Philip de Valois, and he was accordingly crowned king of France. In this decision they displayed the soundest principles of national policy, and Edward ought undoubtedly to have acquiesced.[1] The king of England, however, thought otherwise, and accordingly began to make preparations for an invasion of France.

By doing homage to Philip for the duchy of Guienne, Edward gained time to collect such an army and treasure as were necessary for the enterprise. Two powerful continental allies appeared in his favour; namely, Robert of Artois, who had been excluded from the county to make way for his aunt Matilda, a nearer relative by blood to the preceding count; and James von Artaveldt, a famous brewer of Ghent, and leader of the democratical party among the Flemings. It was at the suggestion of the latter that Edward assumed the title of king of the French, as a pledge that he would pursue his undertaking with inflexibility of purpose. The king of England landed at Antwerp in July 1338; but it was not until more than a year thereafter that he reached the confines of France. His first campaign was unimportant, but in the second he achieved a considerable naval victory on the 22d of June 1340. Flushed with this success, he marched to the siege of Tournay at the head of 100,000 men. Near this town the king of France had encamped himself in a situation so strong as to bid defiance to attack. Edward challenged him to single combat, but this was refused; and the English were at last compelled to raise the siege, and to retire sullen and discontented from the place.

The efforts of Edward began now to be much crippled for want of money. The exchequer of England was unable to satisfy his demands, and his allies had become clamourous for their arrears. Some of his courtiers having instilled into his mind suspicions of the fidelity of his ministers, he suddenly returned to London, where he landed about midnight at the Tower. Next morning he displaced the chancellor, treasurer, and master of the rolls, confined three of the judges, and ordered the arrest of most of the officers employed in the collection of the revenue. Archbishop Stratford, however, boldly opposed his career of resentment and cruelty, and vindicated the cause of the ministers. The king was compelled at last to abandon his process against the primate, for the urgency of his wants admitted of no delay.

The failure of his first two campaigns did not wean Edward from his attachment to foreign alliances. By a disputed succession to the duchy of Brittany, in which he took the part of the individual who opposed Philip of France, a new road was opened up to him into that country. He collected a vast army, with which he landed near Cape la Hogue about the end of July 1346. His career in France was a series of triumphs most glorious to the English arms. On the 26th of August 1346 was fought the decisive battle of Cressy, which is still memorable after the lapse of many centuries. In this celebrated conflict, Edward the Black Prince, a youth only sixteen years of age, gained unfading laurels. The siege of Calais followed, and the place was reduced after an obstinate defence. The first fruit of the reduction of this place was a truce, which lasted till 1355, when Edward the Black Prince, who governed his father's dominions in France, undertook an expedition into the neighbouring provinces, and in the following year carried his arms into the heart of France. The victory of Poitiers was another mortifying humiliation to the French. John their king was taken prisoner, and treated with noble hospitality and respect by his renowned conqueror. He was conveyed to England, where his reception resembled rather the return of a victorious prince than the humiliation of a captive monarch. For a particular account of these and other transactions of the English in France, the reader is referred to the article FRANCE.

During the absence of the king of England on the Continent, his country was harassed by the Scots, who invaded it, but experienced a defeat at Nevelles Cross. In 1355, Edward himself invaded Scotland; and the havoc caused by this expedition was long remembered by the natives. The death of Edward Baliol in 1364 left David Bruce without a rival to the Scottish throne; and the pretensions of the Plantagenets to Scotland were terminated by Edward III.'s recognition of his brother-in-law. See SCOTLAND.

In the mean time Edward the Black Prince, after a Spanish campaign, in which he gained the celebrated battle of Navarete, returned to England in pursuit of health and quiet. But thirty years of toil and war had exhausted his robust frame, and he expired at Canterbury on the 8th of June 1376, in the forty-sixth year of his age. He left behind him a lofty reputation for bravery and skill as a commander, generosity as a knight, and wisdom and vigour as a statesman. His father Edward III. did not long survive his loss. He died on the 21st of June the year following. The reign of this monarch is generally considered by Englishmen as the most illustrious period of their ancient annals. "The victories of Cressy and Poitiers," says Mr Turner, "may have produced the popular sentiment; but the reflective mind will adopt the opinion as steadily, when it observes, during this reign, that our navy established its preponderance over the most celebrated fleets that were then accustomed to navigate the British channel; that our parliament enjoyed, in full and upright exercise, those constitutional powers which the nation has long learnt to venerate as its best inheritance, but which weaker sovereigns have too eagerly contested; that our manufactures and commerce began to exhibit an affluence and an expanding growth, and to be conducted on the true principles of public improvement; that our clergy evinced a disposition to emancipate themselves from the papal despotism, and some to exercise a just freedom of thought on the most important of all human concerns; that the lineaments of our prose literature became distinctly discernible; that the pursuit of the mathematical and natural sciences, and of the art of reasoning, at one or both of our venerable universities, was ardent and successful; that our poetry assumed the attractive form with which its life, sympathy, utility, and immortality are most surely connected; and that our manners displayed a moral sentiment, which, though somewhat fantastic, and always pure, yet contributed to soften the horrors of war, and has led to that more cultivated feeling which, continually increasing and refining, has made Englishmen distinguished for their generosity, magnanimity, and honour." It may be added, on the authority of Sir Mathew Hale, that during this reign the law was greatly improved, and nearly attained its meridian. The monarch himself kept pace with the progress of the time, and his reign was sufficiently protracted to afford opportunities for the development and consolidation of all improvements. He left his country ennobled in the eyes of Europe, and possessed of gigantic energies capable of realising the glorious destinies which awaited her.

---

[1] Turner's *History of England*, vol. ii. p. 144.

Edward III. was succeeded by Richard II. son of the beloved Black Prince. He commenced his reign, being only eleven years of age, on the 22d of June 1377, with many expressions of congratulation from his subjects. His coronation took place on the following year, and parliament was opened with a speech from the Archbishop of Canterbury, which, being "soothing and gracious," was meant to propitiate the favour of the representatives of the nation in behalf of the young sovereign. The Dukes of Lancaster, York, and Gloucester, uncles to the king, with some other noblemen, were appointed regents during Richard's minority. The war, which was still prosecuted in France on a small scale, and the expenses necessary for retaining the towns already taken, required supplies of money, which could not be raised without additional taxation; and this gave rise to much discontent amongst the people. An imposition of three groats upon each person of both sexes and every condition who had passed the age of sixteen, particularly excited the minds of the common people against the government. The manner, too, of collecting this tax, soon furnished an occasion of revolt. The insurrection began in Essex, where a report was industriously spread that the peasants were to be destroyed, their houses burned, and their farms plundered. At Dartford, an individual, well known by the name of *Wat Tyler*, was the first who excited the malcontents to arms. The tax-gatherers proceeded to this man's house whilst he was at work, and demanded payment for his daughter. He refused to comply, on the ground that she was under the age stipulated in the act; upon which one of these fellows offered to prove the contrary in a very indecent manner, and for this purpose laid hold of the maiden. Such insolence, however, roused the spirit of the father, and with one blow he laid the ruffian dead at his feet. A shout of applause burst from the bystanders, who declared themselves prepared to protect Wat from the vengeance of his enemies. The cry of the men of Kent was responded to by those of the neighbouring counties, and Wat soon found himself at the head of an enormous body of insurgents. They advanced to Blackheath in the month of May 1381, and proceeded to enforce their counsels by an attack upon London, in which they succeeded. The king, finding that resistance was vain, agreed to listen to their demands. On this they made a very humble remonstrance; requiring a general pardon, the abolition of slavery, freedom of commerce in the market-towns, and a fixed rent instead of those services required by the tenure of villenage. The king granted all these requests; and charters were made out by which the grant was ratified. In the mean time, another body of these insurgents had broken into the Tower, and murdered the chancellor, the primate, and the treasurer, with some other officers of distinction. They then divided themselves into parties, and took up their quarters in different parts of the city. At the head of one of these was Wat Tyler, who led his men into Smithfield, where he was met by the king, who invited him to a conference, under pretence of hearing and redressing his grievances. Tyler ordered his companions to retire till he should give them a signal, and boldly ventured to begin a conference with the king in the midst of his retinue. His demands were, that all slaves should be set free, that all commonages should be open to the poor as well as to the rich, and that a general pardon should be granted for the late outrages. During the interview, the rebel kept playing with his dagger, and at last he is said to have laid his hand on the bridle of his sovereign's horse; upon which Walworth, lord mayor of London, alarmed for the king, plunged a basillard in the throat of Tyler, and at the same moment another esquire dispatched him with his sword. This is the tale told by the writers of the victorious party, for the partizans of Wat Tyler had no historian to give their version of the story. The insurgents who witnessed the fall of their leader bent their bows with the design of revenging his death. But Richard, though only sixteen years of age, with admirable presence of mind galloped up to them, exclaiming, "What are you doing, my lieges? Tyler was a traitor. Follow me, and I will be your leader." With sullen and wavering discontent they followed him into the fields at Islington, where a body of troops had been collected for the protection of the young king. The insurgents were ordered to return to their homes instantly, and under the penalty of death they were forbidden to skulk about the city during night. But the whole of the rebels did not thus escape, and the revolt was not finally extinguished without much bloodshed and cruelty.

The courage, address, and presence of mind which the king had discovered in quelling such a dangerous tumult, gave great hopes to the nation: but, in proportion as Richard advanced in years, these hopes began to wither; and his want of capacity, or at least of solid judgment, appeared in every enterprise which he attempted. The king had unluckily lost the favour of the common people after the insurrection just mentioned. He allowed the parliament to revoke the charters of enfranchisement and pardon which had been granted; some of the ringleaders in the late disorders had been severely punished, and others were put to death without any form or process of trial. Thus the popular leaders were greatly exasperated by this cruelty, though probably the king did not in this follow the dictates of his own mind so much as the advice of his counsellors. But having thus lost the favour of one party, he quickly afterwards fell under the displeasure of the other also. Conceiving himself to be in too great subjection to his uncles, particularly the Duke of Gloucester, he attempted to shake off the yoke, by raising others to an equal share of rank and favour. Accordingly one of his favourites, Michael de la Pole, was created Earl of Suffolk, and raised to the chancellorship; whilst another, Robert de Vere, earl of Oxford, a young man of an agreeable person, but dissolute in his behaviour, soon acquired an absolute ascendency over him. This nobleman was first created Marquis of Dublin, and afterwards Duke of Ireland, both preposterous and invidious titles. The duke having soon become the dispenser of all the king's favours, a conspiracy was formed against him by some of the most powerful nobility in the kingdom. The Earl of Suffolk was impeached in parliament, and, being convicted of certain charges brought against him, was condemned to pay a suitable fine. Soon afterwards the king was prevailed upon to vest the government in the hands of eleven commissioners along with the three great officers of state. This measure was carried into effect by the Duke of Gloucester, who stood at the head of the committee; and the king could not without regret perceive himself thus totally deprived of authority. He first endeavoured to gain over the parliament to his interests, by influencing the sheriffs of each county, who were then the only returning officers; and this measure failing, he next applied to the judges, who declared that the commission which had deprived the king of his authority was unlawful, and that those who procured or advised it deserved condign punishment; but their sentence was quickly opposed by declarations from the lords. The Duke of Gloucester armed his partizans, and appeared at the head of a body of men sufficient to intimidate both the king and his adherents. These insurgents, sensible of their own power, began by demanding of the king the names of those who had advised the adoption of the late rash measures. A few days afterwards they appeared armed in his presence, and accused by name the Archbishop of York, the Duke of Ireland, the Earl of Suffolk, and Sir Robert Tresillian, one of the judges who had declared in his favour, together with Sir Nicholas Brembre, as public and dangerous enemies to the state. The parliament which met on the 3d of February 1388 condemned the five accused persons to suffer the death of traitors. The Duke of Ireland escaped to Flanders, where he expired four years afterwards; De la Pole died at Paris in the same year; Tresillian and Brembre were put to death, and the Archbishop of York became a Flemish curate, and died in that humble capacity. The other individuals who had subscribed the bold opinion were condemned to perpetual imprisonment; with the exception of Black, who had drawn up the questions, and Usk, appointed under-sheriff to arrest the Duke of Gloucester, who were both executed.

But the king became restive in the traces with which his uncle restrained him. In a meeting of parliament he declared himself competent to manage his own affairs, as he had by this time attained his twenty-second year. This bold announcement was followed by his ordering Thomas Arundel, whom the commissioners had recently appointed chancellor, to give up the seals, which, on the following day, he delivered into the hands of William Wickham, bishop of Winchester. The council was next cleared of the Duke of Gloucester, the Earl of Warwick, and other opposition lords; and the great officers of the household, as well as the judges, were changed for more pliable instruments.

Being now his own master, Richard notified by proclamation that he had taken the reins of government into his own hands; and, whether it was owing to the king or his ministers, it must be owned that for some years his administration was tranquil and happy. During this halcyon period he made a journey into Ireland, in order to divert the melancholy with which he was afflicted on account of the loss of his wife Anne. Soon afterwards he espoused Isabella, a princess of France, then in her eighth year, which contributed to an armistice with that kingdom for twenty-five years.

This alliance with the royal family of France encouraged Richard to execute a scheme of vengeance which he had long nourished in his bosom against Gloucester and others who had been instrumental in the punishment of his favourites. The duke, with the Earls of Warwick and Arundel, were appealed for treason; in consequence of which the former was sent prisoner to Calais, and the two latter committed to the Tower. Here the head of Arundel was shortly after struck off, and Warwick was banished; but the fate of the Duke of Gloucester is involved in some obscurity. On the 21st of September 1397 a writ was issued to Thomas Mowbray, earl marshal, governor of Calais, commanding him to bring the body of his prisoner, the Duke of Gloucester, to answer before the king in parliament to the appeal of treason against him. The reply of the governor of Calais was, that the prisoner had died in his custody. At a subsequent period circumstances transpired which indicate that the duke perished by the foulest murder, doubtless at the instigation of his own nephew. It remains to be mentioned, that at the meeting of parliament, in which these noblemen were impeached, all the acts in which Gloucester had taken a share were annulled, the commission of government was cancelled, the opinions of the judges were declared to be legal, and the judgment against Michael de la Pole was reversed.

After the destruction of Gloucester and the heads of his party, a misunderstanding arose amongst the noblemen who had joined in the prosecution. The Duke of Hereford, son to John of Gaunt, appeared in parliament, and accused the Duke of Norfolk of having uttered treason in a private conversation. Norfolk denied the charge, and offered to establish his innocence by single combat. The challenge was accepted; but the king interrupted the duel, and commanded both the parties to leave the kingdom. The Duke of Norfolk was banished for life, but the Duke of Hereford only for ten years. The former retired to Venice, where he died shortly afterwards. Hereford displayed so much resignation to the will of his sovereign, that the latter commuted the period of his exile to four years. The king had obtained the object of his wishes, namely, the civil destruction of those whose power he dreaded. Even his uncles, either through affection or fear, seconded all his measures, which were now deeply tainted with despotism. On the death of John of Gaunt, "time-honoured Lancaster," the crown claimed his immense estates, to the exclusion of the banished Earl of Hereford, who was pronounced incapable of inheriting them after the judgment which had been pronounced against him in parliament.

By these and other impolitic acts, the king overstrained the bow, and excited a spirit of discontent, which finally hurled him from the throne. The resentment of Hereford had been inflamed by the injury which he had received, and he only waited for a favourable opportunity of retaliation, which soon afterwards occurred.

The Earl of March, presumptive heir to the crown, having been appointed the king's lieutenant in Ireland, was slain in a skirmish with the natives of that country; and Richard, regardless of his precarious situation at home, went over to Ireland with a considerable army, in order to revenge the death of his relative. Hereford, now duke of Lancaster, took advantage of the king's absence. Solicited by the discontented lords, and aware of the alienation of the people from Richard, he embarked at Nantes, and, with a retinue of only sixty persons in three small vessels, landed at Ravenspur in Yorkshire. The Earl of Northumberland, who had long been a malcontent, together with Henry Percy, his son, surnamed *Hotspur* on account of his impetuous valour, immediately joined him with their forces; and the people flocked to him in such numbers that in a few days he found himself at the head of sixty thousand men.

Richard in the mean time continued in fancied security in Ireland. Adverse winds for three perilous weeks together prevented his receiving any news of the rebellion which had broken out in his native dominions; but when the intelligence arrived he was overwhelmed with dismay. Some advised him to sail immediately and face the danger; others recommended that he should first send over the Earl of Salisbury, for the purpose of collecting all who were disposed to support his interests, which plan was adopted. A numerous army joined the earl, but the king protracted his stay in Ireland so long, that on his arrival the whole of this force had melted down to less than an hundred men. To take the field against Henry of Lancaster was consequently out of the question. He therefore proceeded in disguise to the fortress of Conway, where

Salisbury had taken up his quarters. It was the policy of Henry to show symptoms of negotiation, in order to allure the king into his own hands. This he effected in a very deceitful manner. The Earl of Northumberland was dispatched to Richard with a thousand men, who concealed themselves at some distance, whilst the earl proceeded to the fortress where the king was lodged, and by fair promises induced him to quit his stronghold and go along with him to Henry for the purpose of effecting a reconciliation. But during the journey Richard was made prisoner, and finally committed to the Tower to await the judgment of parliament. On Monday the 29th of September 1399, a deputation of lords and commons waited upon the king, and having reminded him of a declaration which he had formerly made at Conway Castle, of his unfitness to govern, and readiness to resign the crown, required his resignation of the regal power. To this he consented, according to the ancient chroniclers, "with a cheerful countenance." During his whole reign, Richard held the sceptre with a wavering grasp, and in the paralysis with which he was now stricken, he as it were unconsciously relinquished it. He likewise recommended Henry his nephew as a fitting successor to the throne.

Before proceeding with the reign of Henry IV. we shall follow the deposed monarch through the few sad weeks of his unhappy life. By parliament he was adjudged "to a perpetual prison, to remain there *secretly* in safe custody." Richard was accordingly consigned to close confinement, and shortly afterwards came to his end, there can be little doubt in an unnatural manner. His fate seems to have been accelerated by a conspiracy amongst his friends to restore him to the throne. The Earls of Kent, Huntingdon, and Salisbury, laid a plot for the destruction of King Henry; but the secret was betrayed, and the confederated noblemen were executed. The death of Richard seems to have immediately followed this unsuccessful enterprise, but the manner of it is involved in impenetrable mystery. According to some chroniclers, several ruffians were sent to the castle of Pomfret, where he had been removed, for the purpose of dispatching him. They rushed unexpectedly into his apartment; but he succeeded in wresting a pole-axe from one of the murderers, with which he killed several of them, but was at length overpowered and slain. Others relate that he was starved in prison, and that he lingered fifteen days before he expired.[1] According to some accounts, he was condemned to suffer this miserable and protracted death; whilst others state that it was a voluntary abstinence, to which he was impelled by despair. He died in the thirty-fourth year of his age, and twenty-third of his reign. It was during the life of Richard II. that Wickliff, the celebrated reformer, promulgated his doctrines in England. See WICKLIFF.

After the throne had been vacated by its legitimate occupant, Henry duke of Lancaster stepped forward and claimed it in right of his being a descendant of Henry III. He was descended from this monarch both by father and mother, but he could not claim by the father's side, because the young Earl of March was sprung from the Duke of Clarence, the elder brother of John of Gaunt, nor by the mother's side, because she was sprung from Edmund of Lancaster, a younger brother of Edward I. It was pretended that Edmund was the elder brother, but it was never proved. By the law of succession it belonged to the descendants of Lionel, the third son of Edward III. That prince died without issue male, and his possessions and pretensions descended to his daughter Philippa, wife of Roger Mortimer, the male representative of the powerful baron who was attainted and executed for the murder of Edward II. the grandfather of the Duke of Clarence. The son of that powerful delinquent had been restored to his honours and estates at a late period of the reign of Edward III. The fourth in descent from the regicide was Roger Mortimer, lord-lieutenant of Ireland, who was looked upon as heir to the crown during the early part of Richard's reign; but his son Edmund Mortimer was only ten years of age when Richard was deposed, so that his claim was easily set aside. Mortimer died in 1425 without male issue, and the pretensions which he inherited through the Duke of Clarence fell to his sister Anne Mortimer, who espoused Richard of York, earl of Cambridge, the grandson of Edward III. by his fourth son Edmund of Langley, duke of York. But from the foregoing pedigree it is clear that during the life of the Earl of March no right to the crown had descended to any branch of the house of York. Henry, however, notwithstanding the inferiority of his title, was unanimously acknowledged by both houses, and was crowned within a fortnight after the deposition of his predecessor. He was the idol of the populace, the master of parliament, and the heir of the fame and possessions of John of Gaunt.

The reign of Henry IV. was little else than a continued series of insurrections. In the very first parliament which he assembled, a great number of challenges were given and accepted by different barons; and though Henry had ability and address enough to prevent these duels, it was not in his power to avoid continual combinations and revolts against himself.

The most formidable of these disorders was that under the Earl of Northumberland. Various causes are assigned for this insurrection. One is, that the resentment of the Percies had been excited by the king denying them the privilege to liberate or ransom their prisoners; for at the battle of Homildon, where the Scotch suffered a defeat, a number of noblemen had fallen into the hands of Hotspur, who commanded the English. The insurgents themselves assigned another cause for the quarrel, and this was probably the real one. In the course of a war with the Welsh, the Lord Grey of Ruthyn and Sir Edmund Mortimer had both fallen into the enemy's hands. The former being a friend to the king, was allowed to be ransomed by his relations; but the latter, who was uncle to the young Earl of March, the lawful heir to the throne, and of course an object of jealousy to Henry, was denied the privilege of being liberated. This fired with resentment the inflammable spirit of Hotspur, who had married the sister of Sir Edmund; his father the Earl of Northumberland, and his uncle the Earl of Worcester, shared his discontent; and amongst them they projected nothing less than the dethronement of the king.

With this view they formed an alliance with the Scots and Welsh, who were to make an irruption into England, at the same time that the Percies were to raise what forces they could in order to join them. The Earl of Northumberland, by a sudden fit of illness, having been incapacitated for active warfare, young Percy took the command, and marched to Shrewsbury for the purpose of joining the Welsh. But the king had assembled a small army, with which it was his intention to act against the Scots; and, knowing the importance of celerity in civil wars, instantly hurried to meet the rebels. He approached Shrewsbury before a junction could be effected with the Welsh; and by his headstrong impatience Percy was impelled to risk an engagement, which at that time he ought to have declined. The evening before the battle he sent a manifesto to Henry, in which he renounced his allegiance, set the king at defiance, and enumerated all the grievances of which he imagined the nation might justly complain. Amongst the charges with which he reproached the king, were those of perjury, murder, and usurpation of rightful property. All this vituperation was productive of no other effect than that of exasperating to the utmost both the king and his adherents.

---

[1] It was at first believed that Richard had effected his escape into Scotland, and that he lived there twenty years. This ancient tradition has been revived by Mr Tytler, in his *History of Scotland*, and he supports his views with considerable ingenuity. The chief evidence upon which he relies consists in charges made by the regent of Scotland for the expenses of the king of England. But Sir James Mackintosh, in a note at the end of the first volume of his *History of England*, gives several cogent, and we think unanswerable reasons for differing from Mr Tytler upon this point, and adhering to the common narrative. Those who feel an interest in this subject are referred to the work above mentioned, and to the appendix to the third volume of Mr Tytler's *History of Scotland*.

The armies were fairly matched, consisting of about fourteen thousand men each, and both leaders were men of approved valour. The action, which took place on the 21st of July 1403, was obstinate and bloody. After a chivalrous display of his characteristic valour, Percy was slain by a random arrow, and with his fall the courage and the confidence of his followers evaporated. They were completely routed, and driven from the field with great loss. Lord Worcester and two other conspicuous individuals were beheaded on the field. The Earl of Northumberand, however, notwithstanding his connection with the rebels, was mercifully treated by Henry. But this lenity does not appear to have quieted the country; for various insurrections, particularly amongst the Welsh under the celebrated Owen Glendower, disturbed the remaining years of Henry's reign. Owen, under the title of Prince of Wales, gained so many remarkable successes over the royal troops, that the king himself publicly attributed them to necromancy. The unconquerable spirit of the Welsh leader actuated all classes of his countrymen, who flocked to his standard from every part in England where they had taken up their abode. Owen remained free and unsubmissive to the English yoke till the close of his career, and the last glimpse which history affords of his patriotic course is as bright as the first.

The reign of Henry was much disturbed, and the language which our great dramatist makes him employ, "uneasy lies the head that wears a crown," is remarkably appropriate from the lips of such a monarch. The swell with which the nation heaved when he ascended the throne never subsided during his lifetime. The position in which he stood with regard to the succession seems to have caused him much concern; for the case was a difficult one. In his first parliament his eldest son Henry was created Prince of Wales; and in 1404 the right of that prince's brothers to reign, in the event of his dying without issue, was recognised by parliament. The most disgraceful feature of Henry's reign was his deadly persecution of those who entertained the new religious doctrines. In his second year was passed that sanguinary act, the first that stains the English statute-book on the subject, which orders heretics to be burned; and many an unfortunate Lollard suffered for his faith during the sway of the Bolingbrokes. A remarkable circumstance occurred in 1405, namely, the capital punishment of a clergyman of the highest rank. Scroop, archbishop of York, was an enthusiastic defender of the claims of the Earl of March, and, being taken in arms against his sovereign, was beheaded without trial, conviction, or defence.

Notwithstanding the act against the Lollards, the doctrines of Wickliff gained ground; and the support which Henry gave the hierarchy did not preclude his parliament from attempting its reformation, and even from despoiling it of part of its possessions.

In 1405 the Commons, who had been required to grant supplies, proposed to the king to seize all the temporalities of the church, and employ them as a perpetual fund to meet the exigencies of the state. When this address was presented, the Archbishop of Canterbury, who then attended the king, objected that the clergy, though they went not in person to the wars, sent their vassals and tenants in all cases of necessity; whilst at the same time they themselves who staid at home were employed night and day in offering up their supplications for the success of the enterprise and the prosperity of the state. The speaker answered with a sarcastic smile, that he thought the prayers of the church but a very slender supply. The archbishop, however, prevailed in the dispute; the king discouraged the application of the Commons, and the Lords rejected the bill which the lower house had framed. The Commons were not discouraged by this repulse; in 1410 they returned to the charge with renewed zeal and determination.

A Lollard had been burnt, and the lower house of parliament, as if in retaliation of this atrocity, presented a schedule to the king, showing that he might have from the temporal possessions of the bishops, abbots, and priors, that were then uselessly wasted, 15 earls, 1500 knights, and 6200 esquires. But the reply of the king was severe, and he forbade them to discuss such topics for the future. They then petitioned that the clergy should be subjected to the civil tribunals, but this was also refused; and a request that the statute against the Lollards might be mitigated shared the same fate.

The reign of Henry was now drawing towards a termination. The last years of his life were darkened by disease, and undistinguished by vigour. He had been subject to eruptions in his face and to attacks of epilepsy. By one of these he was carried off, at Westminster, on the 20th of March 1413, in the forty-seventh year of his age and fourteenth of his reign. Henry owed the English sceptre, not, in the first instance, to his own plotting or ambition, but to a popular revolution against the authority of his predecessor. He landed in England for the avowed purpose of only seizing his own possessions, of which he had been most unwarrantably deprived; but finding Richard a most unpopular sovereign, and his own reputation very high, whilst his affinity to the blood royal was, though not so near as that of the Earl of March, sufficiently so to give him a plausible pretext for standing forward as a candidate for the crown, he accordingly did so, and proved successful. He united in a high degree watchfulness and circumspection, with a bold and decisive policy. For his arbitrary measures he brought forward the plea of necessity, "which," says Sir James Mackintosh, "prevented them from growing into precedents subversive of the constitution." As he owed his throne to popular revolt, so he was in some measure compelled to adopt popular principles. Under his reign the House of Commons advanced with a steady pace towards importance and authority. It assumed a higher and more decisive tone than had hitherto characterized its proceedings, and pushed its inquiries into all the affairs and departments of government.

Henry of Monmouth, eldest son of the preceding monarch, ascended the throne immediately after the death of his father. With the early life of Henry V. we usually associate acts of frivolity, insubordination, and even low vice. But to the creative genius of a powerful poet must in a great measure be attributed this almost universal impression. That he was guilty of delinquencies beneath the dignity of the heir apparent to the English throne, may be true; but there is no satisfactory evidence either to confirm or refute the traditionary stories which are told of him. At an early age he discovered talents of no common order. He was only sixteen years of age when the battle of Shrewsbury was fought, and on that occasion he displayed equal firmness and ability. Afterwards, when intrusted with the guardianship of the Welsh marches, he conducted himself in a manner so highly creditable, that he more than once received the thanks of the House of Commons for his conduct. On his accession to the throne, he made himself popular by several wise and generous measures. He liberated his cousin the Earl of March from the constraint under which that prince, undoubtedly the heir of Edward III., had been held by the jealousy of Henry IV. The Percies, who were exiles in Scotland, he restored to their possessions, and even to a command over their martial vassals. Those ministers of his father who had recommended themselves by their uprightness and decision, were retained in the offices which they held. The chief justice, in particular, who had formerly imprisoned the king, whilst Prince of Wales, for his misconduct, was not only pardoned, but received into high favour. He expressed deep regret for the fate of Richard II., and performed his funeral obsequies with becoming pomp and solemnity. That Henry had a mind which towered above the level of his contemporaries, his remarkable triumphs in France are evidence; but that in some respects he was not in advance of his age, the severities which he practised against the Lollards afford ample proof. The head of that party was Sir John Oldcastle, an individual alike distinguished for his valour and military talents, and who had acquired the esteem both of the late and present king. His high character pointed him out as a proper object of ecclesiastical fury, and he was accordingly denounced to Henry, who, at a private interview, attempted to make him recant his faith; but in vain. Oldcastle was therefore condemned to suffer the death of a heretic; but having effected his escape, he raised an insurrection, which was soon crushed. He succeeded however in eluding pursuit for four years, but he was at last taken and executed as a traitor. After the suppression of the revolt, the most severe laws were passed against the unfortunate Lollards. It was enacted, that whoever should be convicted of Lollardy, besides suffering capital punishment according to the laws formerly established, would also forfeit his lands and goods to the king; and the officers of government were likewise bound by oath to use their utmost endeavours to extirpate the heresy.

The restoration of tranquillity afforded Henry an opportunity of turning his attention to France, the miserable condition of which offered a fair prospect of success to his arms. The claim of his family to the crown of that country was revived; and on the 15th of April 1415 he assembled a great council at Westminster, to whom he announced his determination of making a "voyage in his own proper person, by the grace of God, to recover his inheritance." He appointed his brother, the Duke of Bedford, lord lieutenant of the kingdom during his absence. When about to set sail for Normandy, a rash conspiracy broke out, which detained him for a little time; but it was soon suppressed, and Henry embarked at Southampton with an army of about thirty thousand men, the greater proportion of whom were archers. He entered the Seine, and having reduced Harfleur, he challenged the dauphin to meet him in single combat, and decide the contest for the crown of the country which he had invaded. But this was destined to be competed for on a far wider arena than that which two combatants could occupy. Henry crossed the Somme, and was proceeding on his road towards Calais, when he came up with the enemy at a small village, called by the French Azincourt, and by the English Agincourt. Here was fought a great and decisive battle, which ended in the total defeat of the French army, estimated at not less than four times the strength of that of the English. (See AGINCOURT.) Henry did not immediately pursue his victory, and returned to England, where he was received with the utmost enthusiasm; but he soon afterwards rejoined his troops in France. The claimants for the crown of that kingdom were so numerous, that had he boldly prosecuted his own schemes, the opposing factions might have leagued together against him as a common enemy. It was therefore his policy to remain inactive, and, by tampering with them separately, to foment the discord which prevailed amongst the French leaders. On the 21st of May 1420, a treaty was at length concluded at Troyes, which promised to crown the hopes of the Plantagenets with success, and establish them on the throne of France. The principal articles stipulated the marriage of Henry with Catherine, daughter of the French king; that Henry should be regent of France whilst Charles remained alive; and that he should succeed that monarch after his decease. Henry accordingly espoused the French princess; but he was not long permitted to enjoy his connubial happiness or his good fortune. A fatal malady seized him at Paris; and having been conducted by his own orders to Vincennes, he expired there on the 31st of August 1422, in the thirty-fourth year of his age, and the tenth of his reign.

The name of Henry V. is adorned with all the splendour of brilliant conquest and successful ambition. By a single victory he brought the crown of France within his reach, if not within his grasp. But he had other qualities besides those of a warrior; he was a statesman of consummate skill, as his conduct after the victory of Agincourt sufficiently testifies. His mind was altogether of a superior order, and there seems nothing to prevent his being ranked with the greatest of English monarchs, except the countenance which he gave to ecclesiastical persecutions.

By Catherine of France Henry had a son who succeeded him when not yet a year old. The whole of his long reign is occupied with a war for the French crown, and a disastrous civil war in England between the houses of York and Lancaster. At the accession of Henry VI. parliament ordered a new royal title, in which he was recognized as king of France and England, and lord of Ireland; appointed his father's eldest brother, the Duke of Bedford, protector, defender, and chief counsellor of the kingdom and of the English church; and in his absence invested the Duke of Gloucester, his younger brother, with these honours. A council was named, and certain articles enacted, for the purpose of limiting the power of the protector. The kingdom of France was now in the most deplorable situation. By the solemn investiture of the infant king of England with the royal prerogative in that country, Charles VII. succeeded only to a nominal kingdom; for the greater portion of it adhered to the interests of Henry. But notwithstanding all these advantages, the English daily lost ground, and in the year 1450 they were finally expelled from the country. See the article FRANCE.

It may be easily conceived that such a train of bad success was likely to be productive of discontent at home. Continual animosities were kept up amongst the king's counsellors during the first thirty years of his nominal rule. This tended to plunge the nation in convulsions, and prepare it for becoming the theatre of a sanguinary civil war. Humphrey duke of Gloucester was envied by many on account of his high station. Amongst these was Thomas Beaufort, bishop of Winchester, afterwards cardinal, the legitimate son of John of Gaunt, brother to

Richard II. This prelate, to whom the care of the king's education had been committed, was a man of some capacity and experience, but of an intriguing and restless disposition. He had frequent disputes with the Duke of Gloucester, over whom he gained several advantages. The Duke of Bedford employed both his own authority and that of parliament to reconcile them, but in vain; their mutual animosities served for several years to embarrass government, and to lay it open to its enemies. The sentiments of the two leaders were particularly divided with regard to France. The bishop laid hold of every prospect of accommodation with that country; and the Duke of Gloucester was for maintaining the honour of the English arms, and regaining whatever had been lost by defeat or delay. Both parties, therefore, called in all the auxiliaries they could command. The bishop resolved to strengthen himself by procuring a proper match for Henry, at that time twenty-three years of age, and then by bringing over the queen to his interests. Accordingly, the Earl of Suffolk, a nobleman whom he knew to be stedfast in attachment to him, was sent over to France, apparently to settle the terms of a truce which had then been contemplated, but in reality to procure a suitable consort for the young king.

The bishop and his friends had turned their attention to Margaret of Anjou, daughter of Regnier, titular king of Sicily, Naples, and Jerusalem, but who was destitute of either real power or possessions. She was looked upon as the most accomplished princess of the age, both in mind and person; and it was thought the abilities which she possessed would supply the want of them in her husband, to whom maturity of years had brought no maturity of understanding. He was a child from the cradle to the grave. The treaty was therefore hastened on by Suffolk, and soon afterwards ratified in England. Previously to the king's marriage, however, a conspicuous blow was struck at the protector's greatness. In that age a charge of sorcery was capable of blasting any character, however spotless or pure; and even of throwing odium upon all who were related to the individual accused. It was an irresistible weapon made use of by churchmen for the destruction of their enemies, and it was wielded by the prelate against his political opponent with tremendous force. He brought forward an accusation of sorcery and treason against Elinor Cobham, wife or concubine of the Duke of Gloucester. She was charged with having made an image of the king in wax, which being placed before a gentle fire, gradually dissolved; and it was expected that as the wax wasted away, the strength of the king would also disappear, and that his death would take place when the whole of the image had melted. Three other individuals were implicated in this accusation, which was readily believed. The prisoners were pronounced guilty; the duchess was condemned to do penance and suffer perpetual imprisonment; one priest was hanged, and another died in prison; whilst, to consummate the affair, Margaret Jourdemayn, a reputed witch, was burnt at Smithfield.

The Bishop of Winchester was resolved to carry his resentment against Gloucester to the utmost. He procured a parliament to be summoned, not at London, which was too well affected towards the duke, but at St Edmundsbury, where the prelate's adherents greatly preponderated. As soon as Gloucester appeared, he was accused of treason, and thrown into prison. On the day appointed for him to make his defence, he was found dead in his bed, though without any signs of violence upon his body. This, however, is no proof that he came not by a violent end.

The death of the Duke of Gloucester was universally ascribed to the cardinal of Winchester, who himself died six weeks thereafter, without leaving behind him so good a name as his political adversary. The Lancasterian party was thus deprived of its chiefs: no male Plantagenet of that lineage remained except the king, who was at best but an apology for one.

After the demise of the cardinal of Winchester, Suffolk governed with uncontrolled sway. But his conduct was obnoxious to the rest of the nobility, who now concerted measures for his destruction. In the year 1447 he was impeached of high treason on various charges. He was accused of exciting the French to invade England, in order to depose Henry and place on the throne De la Pole's son, who was to marry Somerset's daughter, considered by the Lancasterian party as the next in succession to the crown. He was also charged with the loss of France by his negotiations in that country, and with revealing state secrets to the French ministers. Other illegal acts were ascribed to him in the bill of impeachment; and so strong did the current of opinion run against him, that, whether guilty or not, the king was compelled to banish him from the kingdom. But this did not satisfy his enemies, who looked upon expatriation as a sheltering from justice rather than as a punishment. The captain of a ship was therefore employed to intercept him in his passage to France; and, having been seized near Dover, his head was struck off in a small boat, and his body consigned to the waves.

The complaints against Henry's government were heightened by an insurrection, headed by an individual of equivocal descent, but who has been transmitted to posterity by the name or nickname of Jack Cade. He assumed the honourable name of John Mortimer; and having assembled a great body of the peasantry of Kent, he marched to Blackheath. A message was sent to him by the king, demanding the cause of the insurrection. The audacious Cade answered in the name of the community, that their purpose was to punish evil counsellors, and to obtain a redress of grievances. Henry assembled a force; but part of it having been defeated, the remainder refused to fight, and the king retired from the field. Lord Say, the treasurer, was committed to the Tower, in order to satisfy the revolters. In the mean time, the citizens of London opened their gates to the victorious rebel, who made a triumphant entry into the city arrayed in the shining armour and gilt spurs of a knight. For some time he maintained great order and regularity amongst his troops. He always led them out into the fields in the night-time, and published several edicts against every kind of plunder and violence. His followers, however, were not to be thus restrained. Lord Say, without any trial, was beheaded; and soon afterwards, the insurgents, having committed some irregularities, were shut out of the city by the inhabitants. Cade endeavoured to force his way back to his quarters, when a bloody scuffle ensued, which was only terminated by the approach of night. The Archbishop of Canterbury, and the chancellor, who had taken refuge in the Tower, hearing how matters stood, drew up an act of amnesty, which was privately circulated amongst the rebels. This had an electrical effect upon them, and in the morning Cade found himself totally abandoned by his followers. He effected his escape, but was afterwards captured and slain. A number of circumstances now contributed to revive the long dormant pretensions of the house of York to the throne. France had been lost; the arms of England had been disgraced; Margaret the queen, by violence and arrogance, was most unpopular; the king himself was a perfect cipher; whilst, in strong contrast to him, appeared the Duke of York, a man of popular virtues, and the legitimate heir to regal power, according to the English laws of real inheritance. All the males of the house of Mortimer were now extinct; but Anne, the sister of the last Earl of March, having espoused the Earl of Cambridge, who had been beheaded for treason in the reign of Henry V. had transmitted her latent but unforgotten claim to her son Richard. This prince, descended by his mother from Philippa, only daughter of the Duke of Clarence, third son of Edward III. stood plainly in order of succession before the king, who derived his descent from the Duke of Lancaster, fourth son of that monarch. The duke was a man of valour and abilities, as well as of some ambition; and he thought that the weakness and unpopularity of the present reign afforded a favourable opportunity for asserting his title. The ensign of Richard was a white rose, and that of Henry a red one; circumstances which gave names to the two factions who were now about to deluge the kingdom in blood.

The Duke of York was in Ireland during the proceedings against Suffolk and the sedition of Cade. In September 1450 he returned to England, a circumstance which excited considerable alarm at court. He advanced upon London; and, proceeding to the palace at Westminster, knelt before the king, and, deploring the state of the kingdom, entreated him to summon a parliament. The queen appears to have evinced her usual arrogance upon this occasion; but York succeeded in extorting a promise from the king that he would comply with his request, upon which he retired to his castle at Fotheringay. He was scarcely gone, however, when the Duke of Somerset returned from France, and was chosen favourite adviser of the king. The session of parliament proved unquiet and stormy. York presented a complaint against the administration of Somerset, and in the year following exhibited several articles of impeachment against him. But the power and influence of the queen rendered his efforts fruitless. Legal prosecutions became thus inadequate to suit the feelings of the enraged York, and he accordingly assembled an army. The king, doubting his ability to triumph by opposing force to force, affected to acquiesce in the demands of the duke, and put Somerset under restraint. Upon this York disbanded his troops, and retired unattended to the royal pavilion, where he was immediately made prisoner, and compelled to take an oath of allegiance to the king. Somerset rose higher in favour than ever, and completed his ascendency in the government by obtaining the entire confidence of the king and his consort.

On the 13th of October 1453 Queen Margaret presented her husband with a son and heir, the ill-fated Edward prince of Wales. Not long afterwards the king sunk into a state of mental as well as bodily incapacity, and the star of York again appeared above the horizon. The total imbecility of the king having been ascertained, the Duke of York was chosen protector and defender of the kingdom. Previously to this event Somerset had been removed from the palace of the queen to the Tower. The king's malady was not permanent, and on his recovery he put an end to the protectorate, released Somerset from his confinement, and reinstated him in his honours. This was a mortal blow to the peace of York; and having conferred with the powerful Earls of Warwick and Salisbury, who united themselves to his interests, he took the field with the declared intention of only expelling Somerset from the government. But this nobleman's fate involved that of the house of Lancaster. It was in vain that the king attempted a reconciliation of interests; he was compelled to have recourse to arms, and meet the Yorkists in open warfare. A battle took place at St Albans, in which the royalists were totally defeated; Somerset, the immediate cause of the conflict, having fallen in the action.

The king relapsed into his former state, and the Duke of York was a second time chosen protector; but the queen, who could not brook the idea of his continuing at the head of government, procured his dismissal. She is even charged with having conspired his destruction, and that of his most conspicuous adherents. A temporary reconciliation was effected, but discord was again introduced; and the parties having irrecoverably lost confidence in each other, prepared for the deadly struggle of arms.

The forces of the Duke of York under the Earl of Salisbury gained an advantage over the royalists at Bloreheath; but a fatal desertion on the part of York's troops at Ludlow turned the balance in favour of the king; and York fled to Ireland, where he was joyfully received.

But this disaster, though in appearance it suppressed the party of York, was far from being fatal to its power. The snake was scotched, not killed, and it only waited a favourable opportunity for darting on its victim. This soon presented itself. Warwick, who had retained the government of Calais, landed in Kent, and, being joined by a number of barons, advanced upon the capital, which he entered amidst the acclamations of the people. The number of his troops had now so much increased that he found himself in a condition to encounter the royal army. Early in July 1460 he came up with them at Southampton, and a bloody battle ensued, in which the king was taken prisoner, and his army utterly dispersed. Meanwhile the Duke of York having returned from Ireland, openly laid claim to the crown. In the House of Lords the cause of Henry and the Duke of York was solemnly debated; and the latter, though a conqueror, did not absolutely gain his cause. It was determined that Henry should possess the throne during his life, and that the Duke of York should be appointed his successor, to the utter exclusion of Henry's offspring.

Though the royal party now seemed destitute of every resource, the queen still retained her intrepidity, disdaining every arrangement which implied the dethronement of her child. Wales seemed the natural place of refuge for the mother of him who was called its prince, and thither accordingly she fled. This warlike dame assembled a considerable army to rescue her pusillanimous husband, and marched to the northern provinces, where Northumberland and Clifford joined her with their borderers. This union having alarmed the victorious party, York and Somerset hastened to anticipate their designs, and, having assembled a sufficient force, succeeded in reaching the strong castle of Sandal before Christmas. Actuated by the pride of prowess and the impatience of inaction, York engaged the queen's army with one of inferior force. The conflict took place at Wakefield on the 30th of December 1460, and terminated in the total defeat of the Yorkists. The duke himself was either slain in the action, or put to death after it; whilst the Earl of Salisbury was taken during the night, and decapitated next day. But no one was so much lamented as the young Earl of Rutland, the son of York, a boy in the twelfth year of his age. He was made prisoner, and coolly stabbed to the heart by Clifford, in revenge for the death of his father, who had perished at the battle of St Albans.

After this victory Margaret marched towards London, in order to set the king at liberty; but the Earl of Warwick, who had now put himself at the head of the Yorkists, led about the captive king in order to give a sanction to his proceedings. Except by the countenance which his presence seemed to give to the transactions of the Yorkists, he was as inert an instrument in their hands as the royal standard which waved above their lines. Warwick engaged the queen's forces at St Albans; but, through the treachery of Lord Lovelace, who deserted with a considerable force during the heat of the action, Warwick was defeated, and the pageant king fell once more into the hands of his own party.

The submission of the city of London seemed now to be all that was wanting to complete the queen's success; but Warwick had secured it in his interests, and the citizens refused to open their gates to the royal victor. In the mean time, young Edward, eldest son of the late Duke of York, put himself at the head of his father's party. He was now in the bloom of youth, remarkable for the beauty of his person and for bravery; and he was, moreover, a very great favourite with the people. He defeated Jasper Tudor, earl of Pembroke, at Mortimer's Cross in Herefordshire; the earl himself being taken prisoner, and immediately beheaded by Edward's orders.

Meanwhile he was joined by the remainder of Warwick's army, and the united forces entered the metropolis amidst the applause of the people of the city and of the surrounding provinces. Edward laid his claim before a council of lords, and on the 4th of March 1461 he was proclaimed king by the style and title of Edward IV.

But notwithstanding all her disasters, the queen remained inflexibly devoted to her purpose. She retired to the northern counties, where such numbers flocked to her standard that her army very soon amounted to sixty thousand men. Edward IV. was a voluptuary, but he never allowed his activity and vigilance to slacken. With Warwick and an army of forty thousand men he commenced his march to the north. The hostile forces met at Towton, in the county of York, on the 29th of March 1461, and an obstinate engagement ensued, which continued during the night, and was renewed with the utmost fierceness on the following morning. The queen's army was totally defeated, and, as quarter was given on neither side, the slaughter was dreadful. Between thirty and forty thousand persons perished in these two bloody days. After this disaster the queen with her husband took refuge in Scotland, whilst Edward returned to the metropolis, where he was crowned on the 29th of June 1461. For three years Edward IV. possessed the throne without any serious insurrection having taken place on the part of the Lancasterians. But during this period Queen Margaret was making strenuous exertions both in France and Scotland to raise a force capable of taking the field against Edward. Having collected a small army, she made an inroad into England, but after several indecisive skirmishes she was totally defeated at Hexham, in Northumberland, on the 17th of May 1464. The Duke of Somerset, who commanded for her, was beheaded; and a number of gentlemen were also executed at York, with little form of law or justice.

By these repeated misfortunes the house of Lancaster became so effectually reduced that Margaret was obliged to separate from her husband, and both were compelled to seek their safety in individual flight. The king was still protected by some of his friends, who conveyed him to Lancashire, where he was at last discovered, and consigned to the Tower as a prisoner. The queen made her escape through Scotland into France, along with her son, and his famous preceptor Sir John Fortescue.

In the mean time King Edward vigorously applied himself to the affairs of government. Feeling secure on the throne, he now also began to give way to the gratification of his amatory passions, to which he was exceedingly prone. In order to divert his mind from such debasing indulgences, the Earl of Warwick, hitherto his steady friend, advised him to marry. Edward consented, and the earl was appointed to negotiate a match with the Princess Bonne of Savoy. He was successful in his mission, but before the conclusion of the marriage treaty the king privately espoused a lady of whom he had become enamoured, and who resisted all his efforts to form an illicit connexion. This lady was Elizabeth, daughter of Sir Philip Woodville, and relict of Sir John Grey, a Lancasterian, who had fallen at the second battle of St Albans. The parties were solemnly united in marriage on the 1st of May 1464, and the bride was acknowledged and in due time crowned. This transaction highly displeased Warwick, who afterwards became still more disgusted at the favour shown to the queen's party, his own and his sovereign's natural enemies. A plan of revenge was therefore set on foot, and a most powerful conspiracy was also formed against Edward. To accomplish his aim, Warwick not only employed his own influence, which was very extensive, but likewise that of the Duke of Clarence, Edward's brother, on whom the earl had conferred the hand of his daughter without the king's permission. The effects of Warwick's secret combination with Clarence, his own brother Montague, and the discontented nobility and gentry, soon began to appear. Sedition was fomented throughout the country, and a popular insurrection at last broke out in Yorkshire, where Robin of Redesdale, a hero amongst the moss troopers of the border, appeared at the head of sixty thousand men. The articles of their manifesto were principally directed against the king's counsellors and the church.

Henry earl of Pembroke was sent against them with a body of seven or eight thousand men. He was joined by Lord Stafford with five thousand more troops, and the two commanders prepared to meet the insurgents. They at first received a repulse, but it was of no material importance. An unfortunate dispute, however, between Pembroke and Stafford, caused the latter to march off the field with his troops; and in a battle which immediately afterwards ensued, the royalists were cut to pieces, and their commander taken prisoner and beheaded.

The king, enraged at this, caused Stafford to be executed in a like summary manner. This event completed the disaffection of the king's followers, who now deserted him in thousands; and he himself was at last taken prisoner by Warwick and his friends; but this conquest embarrassed the confederated nobles. The detention of the king was not popular; and the military refused to act until he was released, which took place accordingly, and a reconciliation was effected. The truce was, however, of short duration. A new insurrection broke out in Lincolnshire, in which Warwick and Clarence were deeply involved. The rebels were commanded by Sir Robert Welles, son to a nobleman of the same name. Under an alleged charge of treason, the latter was beheaded by the king, who marched against the insurgents with his usual celerity, and gave them a total overthrow at Erpingham, in Rutlandshire, on the 12th of March 1469. Warwick and Clarence again attempted to entrap Edward, but having failed of success, they escaped to France.

Louis XI. openly espoused the cause of the malcontent barons, and effected a reconciliation between them and the fugitive Queen Margaret. Their mortal enmities were reconciled in common hatred of the king of England. A treaty was concluded, which stipulated that Edward should espouse Anne Neville, Warwick's daughter, and that they should combine their efforts to restore Henry to the throne of which he had been deprived. It was likewise agreed upon, that in case of failure of issue by the prince, the crown should descend to Clarence. After these preliminary arrangements, Warwick assembled a small force, and set sail for England, where he landed whilst Edward was in the north suppressing an insurrection which had there broken out. This seems to have been an artifice practised by a brother-in-law of Warwick's, who thus drew the incautious monarch to a distant part of the kingdom, and left the southern counties open to the invader. Warwick was a great favourite with the people, the subject of popular ballads, which resounded his praise throughout every town in the kingdom. Thousands having flocked to his standard, he advanced upon London, and there proclaimed Henry VI. The usual activity of Edward seems to have forsaken him, or else his pernicious frivolities had alienated the affections of his troops, whose fidelity towards him likewise decreased as Warwick drew near to them. Edward was compelled to fly to Holland, Clarence and Warwick made their triumphal entry into the capital, and Henry was formally restored to regal authority. But those who had reinstated him had placed only a barren sceptre in his grasp, for the real power resided with them. Edward was pronounced an usurper, and all acts passed under his sanction were repealed. The crown was settled on the male issue of Henry VI., and in default of such issue, on the Duke of Clarence and the heirs of his body. But Edward's party was not yet destroyed. After an absence of nine months, he, seconded by a small body of troops granted him by the Duke of Burgundy, made a descent at Ravenspur in Yorkshire. At first he met with little success; but his army increasing on his march, he was soon in a condition to appear before the capital, which instantly opened its gates to receive him.

The unfortunate Henry was thus again plucked from the throne; and the hopes of Warwick were almost totally blasted by the defection of Clarence, Edward's brother. He however advanced to within about ten miles of London, resolving to wait the approach of Edward, and took a position at Barnet, where, on the 14th of April 1471, a battle was fought, more remarkable for its consequences than for the number of the slain or the obstinacy of the combatants. Considering the animosity existing between the parties, the general slaughter was unusually small; but amongst the fallen were Warwick and his brother Montague; and the death of the first of these individuals was of far more importance to Edward than the victory which he had gained. It broke the charm which associated with his name the certainty of victory and success to the caûse which he espoused. On account of the remarkable transactions in which he had been engaged, he received the appellation of "the king-maker." His death also destroyed the greatness of the house of Neville.

At this time the queen had just returned with her son from France, where she had been soliciting supplies. She had scarcely time to refresh herself from the fatigues of the voyage, when she received the fatal news of the death of Warwick, and the total destruction of his forces. All her resolution was unable to support her under this calamity, and she sunk to the ground in despair. Upon recovering herself, she took sanctuary in the Abbey of Beaulieu in Hampshire, where she still found friends ready to assist her. Tudor earl of Pembroke, Courtenay earl of Devonshire, the Lords Wenlock and St John, with some other men of rank, encouraged her yet to hope for success, and promised to stand by her to the last. On this assurance she resumed the undaunted bearing which was natural to her, and, advancing through the counties of Devon, Somerset, and Gloucester, collected a considerable army. The hostile forces came in sight of each other at Tewkesbury on the 14th of May 1471, where a battle was fought, which decided this sanguinary war. The queen's army was totally defeated; the Earl of Devonshire and Lord Wenlock were slain in the conflict; the Duke of Somerset, and about twenty other persons of distinction, who had taken shelter in a church, were surrounded, dragged forth, and immediately beheaded; about three thousand of their soldiers fell in battle, and the rest were entirely dispersed. Queen Margaret and her son were taken prisoners, and brought to the king, who asked the prince how he dared to invade his dominions. The youth replied that he came hither to claim his just inheritance; upon which Edward struck him on the face with his gauntlet. The Dukes of Clarence and Gloucester, Lord Hastings, and Sir Thomas Gray, taking this blow as a signal for further violence, hurried the prince into the next apartment, and there, it is said, dispatched him.[1] Margaret was thrown into the Tower along with her husband Henry, who there closed his unhappy career a few days afterwards. The Duke of Gloucester has been charged with his murder, but there is no proof of the fact.[2] Margaret was ransomed by the king of France in 1475, for fifty thousand crowns. She survived her deliverance about seven years, during which time she lived in France, withdrawn from the tumults of state.

Edward being now freed from all his enemies, began to inflict punishment on those who had formerly appeared against him. Amongst the cruelties which he committed, that on his brother the Duke of Clarence was the most remarkable. They had been formally reconciled to each other; but this hollow truce to fraternal animosity was broken by a singular incident. Whilst the king was one day hunting in the park of one Burdett, a servant of the duke, he killed a white buck which was a great favourite of the owner. Burdett, concerned at the loss, broke into a transport of rage, and declared that he wished the horns of the deer were in the belly of the person who advised the king to that insult. For this exclamation Burdett was tried for his life, and executed at Tyburn. Clarence exclaimed against this sentence as iniquitous, for which he was attainted of treason, and charged with sorcery, in order to give to Burdett's expressions the dignity of necromantic imprecation. Sentence of death was pronounced against him; but the king having some repugnance to order the public execution of a brother, he was dispatched in private. There was a rumour prevalent at the time that he was drowned in a butt of malmsey wine, to which he is said to have been very partial; but there is no proof that his murder was effected in this manner.

The remainder of Edward IV.'s reign is unimportant. A war with France, which followed the civil wars in England, terminated in 1475 without being characterized by any memorable events. But the foolish idea of aggrandisement in France was still popular with the people, and Edward employed a considerable portion of the latter years of his reign in making apparent preparations for reviving the pretensions of his predecessors to the crown of that country. It does not appear, however, that he ever had any intention of carrying his threats into execution. Edward died on the 9th of April 1483, in the forty-second year of his age and twenty-first of his reign, calculating from the period of his first assuming the crown. In the character of Edward IV. we see a combination by no means singular of great and vicious qualities. As a commander he possessed decision, promptitude, daring, and valour, in a remarkable degree; in these respects indeed he surpassed all his competitors. But the laurels which he won in the field were stained by many cool-blooded atrocities, which altogether deprive the individual who perpetrated them of any claim to real greatness. He was cruel and faithless, and no barrier was capable of restraining him from indulging in sensual gratifications. Besides five daughters, he left two sons; Edward prince of Wales, his successor, then in his twelfth year; and Richard duke of York, then in his eleventh year.

---

[1] Such is the account commonly given of the death of this scion of the house of Lancaster. It is worthy of remark, however, that the Harleian manuscript not only gives no sanction to this popular tale, but expressly declares that the prince was slain in the field.

[2] A reader of the present day who can calmly dispossess his mind of the poetical associations with which the subject is invested, will probably agree with a historian who has minutely investigated the subject, that Gloucester is to be exculpated from the charge of murder in this case. (See Turner's *History of England*, vol. ii. p. 375.)

On the death of Edward IV. the kingdom was divided into new factions; and those of the queen's family, who, during the last reign, had come into power, were obnoxious to the old nobility, who looked upon them as upstarts and inferiors. The king had endeavoured to prevent these animosities proceeding to any extent, by desiring on his death-bed that his brother Richard duke of Gloucester should be entrusted with the regency; and he recommended peace and unanimity during the minority of his son. But the monarch was no sooner dead than the former resentment between the two parties burst forth with violence; and the Duke of Gloucester, to whom it is customary to attribute every bad quality, resolved to profit by their contentions. As soon as he learned the tidings of his brother's death, he proceeded to Ludlow Castle, where Prince Edward then was under the charge of Lord Rivers, his uncle by the mother's side. This nobleman was charged by Gloucester with having instilled into the mind of his young ward unfavourable opinions of the protector, and under this groundless accusation he was put into confinement, along with others of the Woodville family. Gloucester, with Buckingham, his noted accomplice, marched to London with Prince Edward, and the other young prince's person having also been secured, both of them were consigned to the Tower, under the specious pretext that they would there be safe from the machinations of their enemies. The coronation was postponed from the 4th of May till the 22d of June, so that the secret purposes of the protector began to be unveiled; and it would seem probable that Hastings and Stanley, the friends of the late king, began to show some misgivings as to the designs of Richard. At a council held in the Tower on the 13th of June 1483, Hastings was seized, and soon afterwards executed upon a log of timber, without any form of trial. Stanley and other obnoxious lords were thrown into various dungeons; and on the same day Earl Rivers and some others were executed at Pomfret Castle, on the most unjust pretences of treason.

The protector now considered himself as in a situation to lay claim to the throne. He used his utmost endeavours to inspire the people with a notion of the illegitimate birth of the late king, and that his children were not only illegitimate on this account, but also because their father had been secretly wedded to Elinor Butler previously to the solemnization of marriage between him and Elizabeth Woodville. Shaw, a popular preacher, was hired to harangue the people to this effect from St Paul's cross. The number of Edward's amours gave some plausibility to these rumours, and prepared the minds of the people for the usurpation of the crown by Richard. Two days afterwards Buckingham harangued the populace in much the same manner as Shaw; and on the 25th of June 1483, that nobleman presented Richard with a parchment purporting to be a declaration of the estates of parliament in favour of the protector, as the only legitimate prince of the house of York. Richard, with his usual dissimulation, evinced some hesitation upon the point; but on the following day he took possession of the crown, and from the 26th of June 1483 is accordingly dated the commencement of his reign.

The only obstacles which now interposed between Richard and the peaceful possession of the crown were his two nephews, whom he still kept in the Tower, for the sake of safety, as he miscalled their imprisonment. During a progress through the kingdom a confederacy was formed against him, and meetings were held, which had for their object the liberation of the princes. But this was unnecessary, as they had been privately dispatched by the king's orders. The manner of their death was kept a profound secret, and it is very doubtful if even yet we are acquainted with the real facts. The most probable account, however, is, that Richard having tampered in vain with Brackenbury, the governor of the Tower, to put them to death, found a ready instrument for the execution of his diabolical purpose in Sir James Tyrrel, his master of the horse. This individual, with two other ruffianly associates, having obtained access during the night to the apartment of the princes, smothered them as they lay asleep, and buried their bodies at the foot of the staircase.

Richard having thus secured himself on the throne, attempted to strengthen his interest by means of foreign alliances, and also by procuring the favour of the clergy at home; but he found his power threatened from a quarter where he least expected an attack. The Duke of Buckingham, who had been so instrumental in raising him to the throne, either thinking his services inadequately rewarded, or for some other causes which cannot now be ascertained, instigated a revolt against Richard. The horror with which the intelligence of the midnight murder in the Tower was received prepared the public mind for seconding the designs of Buckingham, who, with several other leading individuals in the kingdom, now declared for Henry, the young Earl of Richmond, in opposition to Richard. The earl, at this period an exile in Brittany, was considered as the chief of the Lancasterian party. His right to the crown by succession was, however, very equivocal; but the cruel behaviour of Richard inclined the people generally to favour his pretensions; and, in order to give an additional strength to his title, a match was projected between him and the Princess Elizabeth, the eldest daughter of Edward IV., which, by uniting the two rival families, would put an end to those dissensions which had so long distracted the kingdom and deluged it with kindred blood. Messengers were accordingly dispatched to give him information of the conspiracy, which fortunately escaped the usual vigilance of Richard; and, in about a fortnight afterwards, Richmond returned an answer, which was no sooner communicated to his friends than it reached the ears of the king. The latter immediately summoned his adherents to join him with their retainers at Leicester; and after proclaiming Buckingham a traitor, he marched against him at the head of his army. In the mean time storms interrupted the voyage of Henry; and the army of Buckingham, dispirited by broken bridges and impassable currents, broke up and dispersed. A price was set upon the head of Buckingham, who fled, but was betrayed into the hands of Richard, and immediately put to death.

Richard, now emboldened by his success, employed every means of confirming his title to the throne, and destroying the plans of the exiles and malcontents. He summoned a parliament, the first which he had ventured to call together; and an act was passed declaring him undoubted king of the realm, and settling it upon his son Edward, prince of Wales. The marriage of Edward IV. with Elizabeth Woodville was declared null, and his son pronounced a bastard: then followed a severe bill of attainder, in which several noblemen, bishops, knights, and gentlemen, were deprived of their estates, honours, and rights.

But notwithstanding all the measures of severity adopted by Richard, he was seriously alarmed at the projected marriage between Henry of Richmond and the eldest daughter of the late king. To defeat this project, therefore, now became the chief policy of the king. The princess was induced to quit her sanctuary and come under the protection of Richard, who probably had destined her for his son; but the death of that prince forced him to alter his plans, and secure her for himself. Lady Anne Neville, Richard's queen, was in infirm health, and this induced him secretly to make an offer of his hand to the young princess, which she agreed to accept. During the illness of Anne, Elizabeth discovered, it is said, an unnatural degree of impatience, and hinted her surprise at its duration; a most suspicious circumstance. Her apprehensions, however, were soon allayed. In less than a month the queen died; but her hopes of sharing the throne with Richard were not realized. The match was so very unpopular that the royal wooer was dissuaded from his purpose, and his attention was soon directed to another quarter.

The crimes of Richard had alienated the greater portion of the York party from his interests; and a union between Elizabeth and Henry, for the purpose of reconciling conflicting factions, became a topic of serious consideration. The latter prince again conceived the hopes of seizing the crown by another invasion of England; and having collected an army of three thousand men, he set sail from Harfleur early in August 1485, and landed at Milford Haven on the 6th of that month. Richard affected to hear the intelligence with joy; and displaying the vigilance and activity of his brother Edward, he marched from London on the 16th. His competitor had directed his march through the northern districts of Wales, a tract of country in the interest of the Stanleys. Both armies met at Bosworth in Leicestershire, on the 22d of August 1485, where a battle was fought, memorable for having restored tranquillity to the kingdom, which had so long been the theatre of sanguinary civil wars.

The army of Richmond amounted to about six thousand men, that of the king to nearly twice the number; and both prepared for the contest, equally confident of victory. For, notwithstanding the inferiority of Richmond's troops, he was secretly encouraged by the promises of Lord Stanley, who was hastening, with seven thousand men under his command, apparently to join the royalists, but really with the intention of siding with Henry. Stanley continued his march slowly; and on the morning of the battle he took up a neutral station on the wing of either host. The king entrusted his vanguard to the Duke of Norfolk, whilst that of Henry was assigned to the Earl of Oxford; and the two competitors for the crown placed themselves at the head of the main bodies of their respective armies. Richard, taking advantage of a marsh which covered his right flank, ordered a shower of arrows to be discharged into the adverse ranks, which for a moment threw them into confusion. He sent orders to Stanley to join him immediately; but the refusal of that nobleman to comply with his request shook his confidence and also that of his army, which now began to waver. To complete his dismay, he saw Stanley join the ranks of Henry, a circumstance which determined the fortune of the day. But, in order to retrieve it, Richard made a vigorous effort worthy of a better cause. Chancing to observe Henry in the midst of the conflict, he made a dash at him, determined to cut him down or perish in the attempt. He slew with his own hand Sir William Brandon, the bearer of the hostile standard, unhorsed Sir John Cheney, and was within a blow of his rival, when he was overpowered by numbers, struck to the ground, and immediately slain. After his fall resistance was hopeless, and his army broke up and dispersed. The crown which he wore on that day was taken up by Lord Stanley and placed on Henry's head, who was instantly greeted with shouts of "Long live King Henry." Of Richard's army a considerable number were killed in the battle and pursuit, and amongst these were the Duke of Norfolk, and Lords Ferrers, Radcliff, and Brackenbury. The victors lost but few, and none of any note except their standard-bearer. To enhance their triumph, Lord Strange, the son of Stanley, whom Richard had ordered for execution before or during the conflict, escaped in the confusion and rejoined his father. The body of the tyrant was thrown carelessly across a horse and conducted to Leicester, where it was interred with small ceremony.

Of Richard's character little remains to be said. The crimes of which he was undoubtedly guilty almost remove him from the ranks of mankind, and class him with the most ferocious animals. The arguments which have been brought forward in modern times to prove his innocence are inconclusive, and scarcely to be named, when confronted with the mass of evidence which may be arrayed against him. His fall excited no regret, except amongst a few of his partizans, the slaves of his despotic will. How could it? The death of his unoffending nephews must have still been fresh in the memory of his subjects.

The quarrel between the houses of York and Lancaster was now brought to a conclusion. In order to secure the blessings of peace and an undisputed succession, it was necessary for Henry at once to espouse Elizabeth, and, by so doing, to blend the white and the red roses together. There is no concealing the fact that his title to the crown was of a very ambiguous description. It rested on three grounds, first, his marriage with Elizabeth; secondly, his descent from the house of Lancaster; and thirdly, the right of conquest. According to the sagacious Bacon, "he rested on the title of Lancaster in the main, using the marriage and the victory as supporters." But this main support was not a valid one; for even allowing his descent from John of Gaunt to have been legitimate, he was not the nearest descendant of that prince's children. There were several who had claims superior to his; but the individual whom Henry looked upon with peculiar jealousy was Edward Plantagenet, son of the late Duke of Clarence. After the death of this prince's father, Richard sent for him to court, and created him Earl of Warwick, the title borne by his grandfather; but fearing that he might afterwards become a dangerous competitor, Richard had him conveyed to a distant fortress; and one of the first acts of Henry was to change his place of confinement, and put him in the Tower, as a prison of greater security. Elizabeth, who had been his fellow-captive, was ordered to be conducted to the house of her mother in London, whilst Henry himself leisurely followed her to the capital. He was received there with every demonstration of joy, and greeted by the inhabitants as the deliverer of his country. His coronation was delayed for a time, by the breaking out of a dreadful disease, called from its predominant symptom the sweating sickness. But at the end of a month its virulence began to abate, and Henry was crowned on the 30th of October 1485. To heighten the splendour of the ceremony, he bestowed the rank of knights-banneret on twelve persons, and conferred peerages on three. Jasper earl of Pembroke, his uncle, he created Duke of Bedford; Thomas, Lord Stanley, his father-in-law, Earl of Derby; and Edward Courtenay, Earl of Devonshire. At the coronation likewise appeared a new institution, which the king had established for personal security as well as pomp; a band of fifty archers, who were denominated yeomen of the guard. But lest the people should take umbrage at this step, as if it implied a diffidence in their loyalty, he declared the institution to be perpetual. The ceremony of the coronation was performed by Cardinal Bourchier, archbishop of Canterbury. On the 18th of January 1486, Henry was united to the Princess Elizabeth; and his marriage was celebrated at London with even a greater appearance of joy than either his first entry or his coronation.

The reign of Henry VII. was for several years disturbed by plots and insurrections. The people, by a long course of civil war, had become so turbulent and factious, that no governor could rule, nor was any king likely to please them. The violent animosity expressed by this monarch, however, against the house of York, may justly be considered as one of the causes of the extreme proneness to rebellion which was manifested amongst his subjects. Instead of endeavouring to conciliate the affection of the opposite party, he invariably strove to quell them by force and violence. For this purpose, soon after his accession he took a journey to the north of England, where the Yorkists were very numerous, trusting that his presence might overawe them. On his way thither he received intelligence of an insurrection against him, headed by Viscount Lovel, with Sir Henry Stafford and his brother Thomas. The two latter had raised an army, and were marching to besiege the city of Worcester; whilst Lovel was hastening to their assistance with a body of several thousand men. But they were induced to disperse by the offer of a general pardon. Lovel withdrew from his troops, who immediately gave in their submission to the king. The Staffords took refuge in the church of Colnham, near Abingdon; but they were dragged from this sanctuary, as it was found not to possess the privilege of sheltering rebels. The elder brother was executed at Tyburn, but the younger one received a pardon.

Henry returned from his northern tour, and soon afterwards his queen presented him with a son, whom he named Arthur, in honour of the supposed progenitor of the house of Tudor, the renowned King Arthur; but Henry was not permitted to enjoy undisturbed security. He never was at any time popular except amongst his own party; and in the northern counties, particularly, the late King Richard was remembered and spoken of with regret. Henry was hated for his success, and even charged with having put to death the young Earl of Warwick, whom he had imprisoned, as has already been mentioned. It was necessary for the king to exercise extreme caution, on account of the dangers which surrounded him; and hence he is described as having been mysterious and impenetrable. Sir Thomas More remarks that one thing was frequently pretended whilst another was meant; and Bacon says that the king had a fashion rather to create doubts than assurance. The birth of his son seems to have roused his enemies to make some exertions against him; and being destitute of any chief of sufficient ability round whom insurgents might rally with any hope of success, they were urged to make one of the most extraordinary attempts recorded in history. One Richard Simons, a subtle priest of Oxford, took under his charge Lambert Symnel, the son of a tradesman belonging to the same town. The boy was about eleven years of age, comely, and not without dignity and grace in his person. With this individual, who was well tutored to perform the extraordinary part which was to be assigned him, the churchman landed in Ireland, and presented him to the lord-deputy of the county as Edward Plantagenet, earl of Warwick, who had made his escape from the Tower. It seems to have been at first the design of the fabricators of this singular deception to have presented him to the public as the younger of the princes who had been put to death by Richard in the Tower. In order to further this scheme, a report was circulated that one of these princes had made his escape from his assassins. Why this plan should have been changed, and the youthful impostor seduced to personate an individual still living, it is difficult to conjecture; but such is the fact. The Earl of Kildare, to whom he was presented in Ireland, swallowed the bait, and allowed the claims of Symnel without discussion. This nobleman was a zealous adherent of the house of York; and the little colony called the English Pale, long ruled by that party, retained all its ancient attachments. A belief in the identity of Symnel with the Earl of Warwick became universal, both amongst the nobility and the people. He was lodged in the castle of Dublin; the inhabitants universally took an oath of allegiance to him, as the true descendant of the Plantagenets; he was crowned with a diadem taken from the statue of the blessed virgin, and proclaimed king by the title of Edward VI.

Such an unexpected event so alarmed Henry that he would have gone over to Ireland in person to quell the rebellion, had he not dreaded the machinations of the queen dowager in his absence. To prevent any thing of this kind from occurring, it was resolved to confine her for life in a monastery, under pretence, however, that it was done on account of her having formerly delivered up the princess her daughter to King Richard. The royal dame murmured at the severity of her sentence; but the king persisted in his resolution, and she remained in confinement till her death, which did not take place till some years afterwards.

The next measure was to exhibit the person of Warwick to the people. That prince was accordingly taken from the Tower, and conducted through the principal streets of London; after which the procession moved to St Paul's, where great numbers were assembled to see him. Still, however, the fictitious Warwick prospered in Ireland, and being furnished by the Duchess of Burgundy with a body of two thousand veteran Germans, under the command of Martin Swart, a brave and experienced officer, the invasion of England was determined upon. He landed in Lancashire, whence he marched towards York, expecting that the country people would rally round his standard during his march. But in this he was disappointed; the people were unwilling to join a body of foreigners, and were besides kept in awe by the reputation of Henry. Lord Lincoln, therefore, who commanded the rebel army, determined to bring the matter to a speedy issue. Accordingly he met the royalists at Stoke, in the county of Nottingham, and an obstinate engagement took place, which terminated in Henry obtaining a complete victory. Lord Lincoln, with four thousand soldiers, perished in the action; and Symnel with his tutor Simons were taken prisoners. Simons being a priest, could not be tried by the civil power, and was only committed to close confinement. Symnel was pardoned, and made a scullion in the king's kitchen, whence he was afterwards advanced to the rank of falconer, in which capacity he died. Thus ended this most absurdly planned and injudiciously executed revolt; but it was not destitute of good results. It taught the king that the house of York was not to be trampled upon with impunity; for to such an extent had his antipathy to the branches of that family and its adherents been carried, that it was said his own queen was not exempt from the common odium which was thrown upon them. It was asked by the people, why was she, the rightful heir to the throne, not crowned, and invested with the usual insignia of royalty? Henry silenced these rumours by ordering her coronation; and from that period she shared with him the usual honours of royalty.

Having thus to a great extent established his authority at home, he thought of diverting the minds of his subjects from domestic insurrection to foreign enterprise. He does not appear, however, to have had any intention of prosecuting a serious war in a distant country, but he used the pretext as a means of aggrandising himself. A parliament was summoned, which granted the king a considerable sum for prosecuting the war in Bretagne, the only great fief of the French crown which still retained its own prince and its ancient constitution; by force, by policy, or by good fortune, the French monarchs had obtained possession of all the others. But of the supply granted by parliament, only a small part could be raised. The northern counties not only refused payment of their proportion, but rose in revolt, and murdered the Earl of Northumberland, the king's lieutenant. The insurrection, however, was quickly suppressed by the Earl of Surrey. John a Chambre, one of the ringleaders, suffered at York; and Sir John Egremont, the other, escaped to the Duchess of Burgundy, where he had leisure to hatch new schemes of rebellion. The money which Henry by this means obtained, and also in consequence of another grant from parliament, was quietly deposited in his coffers. For although he collected a considerable army, with which he proceeded to Calais, the king had other objects than victory and conquest in view. Some months previously to his landing on the Continent, he had commissioned the governor of Calais to negotiate a peace and alliance with Charles of France, which was formally concluded. To the French monarch the possession of Bretagne was an important object; and Henry, naturally avaricious, agreed to accept about L.200,000 as a reimbursement for the expenses of the expedition. It was also stipulated that the king of France should pay to him and his heirs an annual pension of 25,000 crowns.

But Henry's hopes of a tranquil possession of the crown of England were doomed to perpetual disappointment. His reign was now to be disturbed by one of the most mysterious personages to be met with in English history. About the time when war was declared against France, a pretender to the regal dignity appeared in Ireland, which seems to have been the natural soil for these spurious shoots of royalty. This impostor passed under the name of Perkin Warbeck, but asserted himself to be Richard duke of York, the second son of Edward IV. who, it was alleged, had escaped from the Tower when his brother was murdered. Previously to his appearance in Ireland, he had been heard of at the court of Margaret, his supposed aunt, who interested herself to the utmost in his favour, and fondly styled him the White Rose of England. But he was compelled to quit Burgundy; for Henry had dispatched some ambassadors to the sovereign of that country, with secret instructions to demand either the person of the impostor, or his expulsion from the territories of the duke. Warbeck was received with open arms in Ireland, for the Irish were fanatically attached to the house of York. Several noblemen who had credulously believed in the fraud of Symnel, from which they had just escaped, gave countenance to his pretensions. A deputation was sent to Flanders to ascertain his history; but they had been corrupted by Henry before their landing in Burgundy, and they returned fraught with charges of treason against the disaffected nobility. Some of the most eminent malcontent Yorkists were put to death, and amongst the rest Sir William Stanley, lord-chamberlain, to whom the king had owed his life on Bosworth field. His fate was most mysterious, and the conduct of Henry upon this occasion is open to the most odious suspicions. Sir Robert Clifford, the individual whose information led to these executions, was a confidential Yorkist; and his behaviour towards his own party, so different from what might have been expected, tended to dissolve the ties which subsisted between it and the malcontent exiles.

Three years had now elapsed since the pretender had set forth his claim, and during that period he had never attempted to establish it by legal proof. He began to feel that he stood upon delicate ground, and resolved at once to enforce his pretended right by an appeal to the sword. With a small force collected in Flanders (for he had been for some time absent from Ireland) he made a descent in the neighbourhood of Deal; but the adventurers were attacked by the inhabitants, and all of them driven back to their vessels, or taken prisoners. Warbeck himself made his escape, and returned in despair to Flanders. From this country he was ejected at the instigation of Henry; and after vainly attempting to gain a footing in Ireland, he set sail for Scotland, where he was well received by the young king, who professed a conviction in the justice of his title. King James conferred upon him the hand of Lady Catherine Gordon, a near kinswoman of his own. The adventurer's fortunes being thus suddenly elevated, he, along with the king of Scotland, advanced into England; but not a native sword was unsheathed in favour of the White Rose. The enthusiasm which had been excited amongst the Scots by his first appearance in their country had begun to decline, and during a long truce, which served all the purposes of a treaty of peace between James and Henry, it was agreed to by the former that he should induce Warbeck to quit Scotland. The adventurer, with a few adherents, accordingly departed, and, after touching once more at Cork, and in vain soliciting the aid of Earl Desmond, steered for Cornwall, where he landed on the 7th of September 1497.

His arrival in this part of the country was a politic step, for an attempt to raise a tax there some time before gave rise to an insurrection, which, although quelled, left behind heartburnings and discontent. A considerable body of Cornish men joined his standard, and before he reached Exeter his army amounted to six thousand men. But the king arrived, and preparations were made for a battle; the heart of the pretender, however, failed him at the sight of the royal standard, and instead of risking an engagement for the crown, he withdrew during the night, and entered his name in the sanctuary of Beaulieu in Hampshire. His followers laid down their arms to the king, and his wife also submitted to his authority, and was placed near the person of the queen. From his sanctuary the fugitive was removed by the king to London, where he was ordered to keep within the precincts of the palace. He contrived, however, to make his escape, but, despairing of getting out of the country, surrendered himself to the prior of the monastery of Shene. The monk contrived to prevail with the king to spare his life; but he was condemned to stand in the stocks and make a public confession of his imposture, after which he was committed to the Tower. In this fortress he met with a singular companion, the real Earl of Warwick, who had now been a prisoner for the period of fourteen years. His life had thus been passed in cheerless captivity, for no other offence than that of being the sole survivor of the male descendants of Edward III. The two contrived a means of escape, but they were discovered. Warbeck was executed at Tyburn; and the son of Clarence having been arraigned for high treason, was condemned to death and beheaded on the 28th of November 1499. This deed was worthy of Richard III. It was a cool-blooded murder, aggravated by circumstances; for the harmless and joyless victim was, from his long confinement, reduced to a state of idiocy. The human soul shudders to think of such atrocities, perpetrated in defiance alike of justice and humanity. From the guilt of shedding innocent blood it is impossible to purify the name of Henry VII.

In 1501, the king's eldest son Arthur was married to the Infanta Catherine of Spain; but he survived the marriage only a few months, having died on the 2d of April following. It was agreed upon a short while afterwards, by the parents of the parties, that the widow of the late prince should be espoused by Henry's next son, now Prince of Wales, and afterwards Henry VIII. The union was sanctioned by the pope, who granted a bull, dispensing with any impediment which their affinity might otherwise cause. The eldest daughter of King Henry was conferred upon James IV. of Scotland; an important union, as from this stock sprung all the sovereigns who have since reigned in Great Britain. King Henry, in his own time, was called the Solomon of England; and, without allowing him to possess undisputed claims to so high-sounding a title, the saying recorded of him regarding the Scottish marriage displays no common foresight and sagacity. When some of his counsellors objected to it, on the ground that the kingdom might thereby fall to the king of Scotland, he answered, "Scotland would then become an accession to England, not England to Scotland; the greater would draw the less; it is a safer union for England than one with France."[1]

In the latter part of this king's reign, his economy, which had always been very exact, degenerated into avarice, and his oppressions at last became severe. In Empson and Dudley he possessed two ministers, who did all that inventive minds could suggest, and hearts of stone perform, to gratify a rapacity, which fed with equal appetite on friend and foe. We are informed by one of the wisest of historians and of men, that these individuals had no reputation, otherwise than by servilely following his bent, and that they "shaped his way to those extremities for which himself was touched with remorse at his death."[2] The hoard which the king had amassed by their unjust extortions, and which was mostly kept in "secret places at Richmond," is said to have amounted to nearly L.16,000,000 of our present money. This amount of specie is so enormous as to warrant a conviction that it has been greatly exaggerated. It may be doubted whether the whole circulating medium of the country at that period amounted to the sum which the avaricious monarch is said to have accumulated.

Henry, who had enjoyed an uncommon share of health during his life, was at fifty-two years of age attacked by severe indisposition. He died on the 21st of April 1509, in the twenty-fourth year of his reign, which, although perpetually disturbed by domestic insurrections, was upon the whole prosperous. He was interred in the chapel at Westminster, which still bears his name; one of the noblest trophies of architectural genius produced in any age, and which confers peculiar distinction upon that in which it was erected. There are many acts of Henry's administration, and some of these have already been particularised, which cannot be related but to his discredit. He was mean, sordid, and unamiable in his nature. No tenderness softened his rigid nature, if we except that which he evinced towards his mother; a virtue, however, too common to be praised even in a king. We see no qualities about the man which inspires us with regard for him; but there are many virtues to admire in the ruler. He favoured every national improvement; and, though penurious to excess in ordinary or essentially private matters, he was munificent in public works. He greatly improved the laws of the realm. With respect to these, Lord Bacon remarks, with his usual clearness and sagacity, "his laws are deep, not vulgar; not made upon the spur of a particular occasion, for the present, but acts of prudence for the future, to make the estate of his people still more happy, after the manner of the legislators in ancient and heroical times." He manifested great regard for trade, as is evinced by his excellent laws for promoting it, and by the extended commercial intercourse of the country. He accepted the offer of Columbus to make that most memorable of voyages, in which he lifted the veil that covered a grand division of the globe, and would have patronized it if he had not been forestalled by Isabella. He gave his sanction to Cabot's celebrated voyage (see CABOT), and fitted out a ship to join the expedition. In fine, the country improved under his government, and became steadily attached to his family.

Henry VIII. son of the preceding monarch, ascended the throne on the 22d of April 1509, being then in the eighteenth year of his age. He assumed the reins of government under most auspicious circumstances. His title was undisputed; his treasury was well stocked; commerce was in a flourishing condition; and the kingdom, which now may be supposed to have looked to the youthful monarch with hope and indulgence, was at peace with every foreign power, and quiet in itself. He was prepossessing in person, accomplished in mind, and adroit in every martial and fashionable exercise. But these advantages belonged to an individual whose heart was usurped by debasing passions, and whose mind was cast in the true mould of despotism.

On the 6th of June 1509, Henry and Catherine were finally united in wedlock, and on the 24th of the same month they were crowned with great splendour. One of Henry's first acts was to bring Empson and Dudley, the obnoxious ministers of his father, to trial. As a capital accusation could not be brought against them for merely executing the will of the late king, it was found necessary to indite them for a conspiracy to seize upon London with an armed force during the last illness of Henry. Of this charge, absurd and incredible as it appears to be, these individuals were convicted; and though it seems probable that the king would have been satisfied with imprisonment for life, yet so clamorous were the people for the blood of the culprits, that he was compelled to sign a warrant for their execution, which took place on Tower Hill.

In 1511, Henry entered into a league with Pope Julius II., Ferdinand king of Spain, and other continental powers, against Louis XII. of France. In this alliance the king of England was not a deeply interested individual; but his vanity was flattered with the idea of receiving the title of Most Christian Majesty, which was promised to him by the pope. The object which the confederates had in view was to wrest from Louis some valuable provinces which he had obtained in Italy; and although Henry had no hope of sharing the spoil with them in this quarter, yet the occupation of the French monarch in schemes of aggrandisement beyond the Alps afforded an opportunity to the English of invading France, and reviving the old chimera of conquering that country. The point, whether England should aim at continental dominions, was debated in parliament; and the arguments against it greatly preponderated. But the vanity of Henry was too much flattered to relinquish the scheme. He sent an ambassador to demand of Louis the ancient patrimony of the English crown in France, and this being refused, war was denounced. Parliament granted a supply, and an army was equipped and sent into Spain. But this expedition was attended with no success, and the troops, dispirited and mutinous, returned to England towards the close of 1512. On the north-western frontier of France, however, the arms of Henry were triumphant, and also in Scotland, which had been tempted by French councils to invade England. James IV. with a considerable army under his command, was met by the Earl of Surrey at Flodden, where a bloody battle was fought, in which the Scots were totally routed, and their king, with the greater portion of his nobility, perished. (See SCOTLAND.) Henry received the news of this victory at Tournay, which he had invested, after having demolished Terouanne. The latter city opened its gates to him in eight days; but all parties being now disposed for peace, a general treaty was concluded in August 1514.

[1] Bacon, iii. 409.

[2] Ibid. iii. 379.

With regard to the administration of government in England, when Henry mounted the throne, the leading ministers in the cabinet were, Howard, earl of Surrey, lord treasurer; and Fox, bishop of Winchester, lord privy seal. Amongst the inferior dependents of the court there now appeared an individual, whose ambition and talent enabled him speedily to supplant every competitor. This was Thomas, afterwards Cardinal Wolsey, who, although only the son of a burgess of Ipswich, gradually raised himself to the first offices of state. (See WOLSEY.) His preferment had been rapid beyond all precedent, and this was not likely to be forgiven by an envious world. From the year 1513 to 1515, he had passed through the various gradations, from being bishop of Tournay, to the honours of the cardinalate, and he succeeded Archbishop Worham in the office of chancellor. With respect to the manner in which he executed his duty as a high public functionary, Sir James Mackintosh remarks, that "his administration of justice as chancellor has been celebrated by those who forget how simple the functions of that office then were; and his rigid enforcement of criminal justice appears only to have been a part of that harsh but perhaps needful process by which the Tudor princes rather extirpated than punished criminals, in order to reclaim the people from the long license of civil wars. As he was chiefly occupied in enriching and aggrandizing himself, or in displaying his power and wealth, objects which are to be promoted either by foreign connections, or by favour at court, it is impossible to determine what share of the merit or demerit of internal legislation ought to be allotted to him. His part in the death of the Duke of Buckingham was his most conspicuous crime; yet, after all, it is probable that he was no worse than his contemporary statesmen. The circumstance most favourable to him is the attachment of dependents."[1]

On the death of Maximilian, which happened towards the end of the year 1519, Henry, along with the kings of France and Spain, became a candidate for the imperial throne. The Spanish monarch was the successful competitor, and, to soothe the wounded pride of Henry, he paid him a visit of ceremony at Dover. His principal design in this was to persuade Henry to abandon a projected meeting which was to take place between him and the king of France, the wily emperor dreading that such an interview might be fraught with danger to himself. He was unsuccessful, however, and the two monarchs met between Ardres and Guines in 1520. The place where this meeting was held has been long celebrated under the name of the Field of the Cloth of Gold. The pomp and parade, the tournaments and other sports of the age, exhibited upon the occasion, were on the grandest scale, and peculiarly calculated to delight the young king of England, a creature of impulse, and one who sacrificed policy to temper, and interest to passion. It was thus that the continental monarchs flattered his foibles, and ingratiated themselves into his favour.

About the same time a crime was perpetrated, in the guilt of which both Henry and his minister Wolsey have been implicated; we mean the execution of Edward Stafford, duke of Buckingham. This nobleman was descended from the youngest son of Edward III.; and the principal accusation brought against him was, that he had tampered with a priest who laid claim to the gift of prophecy, and who had foretold that he would yet ascend the throne in virtue of his descent. Several other charges equally absurd, and not amounting to an overt act of high treason, were brought against him; he was tried by a jury of peers, condemned to death, and beheaded on the 17th of May 1521. Upon this occasion the populace vented their indignation against Wolsey, whose subtle policy had brought the sufferer to the scaffold, by loud cries of "the butcher's son."

Wolsey, however, continued to rule with unabated sway from 1521 till 1527. This period is not distinguished by any events of importance, if we except the opposition which the House of Commons offered to the minister in his attempts to raise supplies. That body obstinately disputed these grants, and attempts were made to raise money by the expedients of forced loans and pretended benevolences, which the legislature had already condemned. But these attempts produced a small supply and a great deal of discontent. Wolsey, notwithstanding his unwearied exertions in behalf of his master, never felt himself perfectly secure in his elevated situation. The capricious and tyrannical temper of Henry forbade his ministers to be at ease in any place of trust near his person. The fall of Wolsey seems always to have appeared to himself as an event of very likely occurrence, and these gloomy forebodings were at last realized. The cause of the rupture between the king and him was the divorce of Queen Catherine, which the former had begun to project. But the fall of Wolsey was not the only event connected with Henry's divorce; it ultimately led to one of the most memorable transactions in the history of England, namely, the separation of that country from the communion of the church of Rome.

The doctrines of the reformation, propagated by Luther in 1517, had gained considerable ground in England, and many professed a belief in them, notwithstanding the severe persecution which had been carried on against heretics during some of the preceding reigns. The papal authority, though still very great, had in the space of ten years declined considerably; but a detail of the circumstances connected with this subject is not required in this place. It may be noticed in general, that the reformation in England was facilitated by the undeniable corruption of the clergy, and the experience which many individuals had of, and the partiality which they entertained for, the doctrines of Wickliff. The seed sown by that divine had never been destroyed; and if it did not show itself above ground, it was extending itself underneath, perpetuating a sort of dormant existence, and ready to spring up on the first propitious occasion. Besides, the marriage of King Henry was looked upon by many as in itself illegal, and only sanctified by a dispensation from the pope.

Whether Henry himself, during the early years of his reign, felt any scruples about the validity of his marriage, may reasonably be doubted; for no trace of any thing of the kind can be discovered in his public conduct till the year 1527. The queen was some years older than himself, and was now past the meridian of life. Her personal charms had decayed, and the heart of the royal sensualist could not be attracted by beauty that belonged purely to the mind. She had born him several children, all of whom died in infancy except the Princess Mary, who survived both her parents, and afterwards ascended the throne. It is reported of the inconstant monarch, that he attributed the mortality in his family to the curse of heaven, which blighted his unnatural alliance with Catherine, his brother's widow. But there was another and more powerful circumstance which led him to contemplate a divorce from his queen; this was the love which he had contracted for Anne Boleyn. The charms of this lady had touched his fiery but not unsusceptible heart; and as his passion could not be gratified except by means of an alliance sanctioned by law, he set seriously to work for the purpose of removing the amiable partner of his throne and bed, and placing the youthful beauty in her stead. The secret intentions of the king having become to some extent public, he ventured to ask the opinions of the most eminent ecclesiastics upon the point. The dangers of a disputed succession, if the king should die without male issue, were brought forward as an urgent plea for taking the step which he had in view. He had also recourse to his theological lore, and certain religious scruples connected with his first marriage helped to give a colour of principle to his real desires, and at the same time to impart to them life and warmth. Some of the divines whose counsel was asked declared that no dispensation could authorize a marriage with the widow of a brother; which they proved from a passage in the Pentateuch. Others, who also founded their arguments upon a portion of Scripture, contended that the prohibition referred to by the opposite party was not universal, and might be dispensed with in the king's case, where the first marriage had been unproductive of issue. Cardinal Wolsey, who had a hazardous game to play, coincided with the former, and gave Henry hopes that his petition to the court of Rome would be successful. But Anne was not the individual whom the prelate had in his eye as a wife for the king. He was desirous of wedding his master to a French princess, and, we are informed, threw himself on his knees before Henry, and entreated him to desist from a project so unworthy of his birth as an alliance with the Boleyn family. But the pliant mind of the cardinal yielded to the impetuosity of his master and to the force of circumstances; and he found it necessary to atone for his indiscreet zeal by displaying redoubled activity to promote the marriage with the lady upon whom the king had fixed his affections. The illustrious Sir Thomas More declined to support the divorce, and Fisher bishop of Rochester acted with the same integrity.

---

[1] *History of England*, vol. ii. p. 121.

A deputation was sent to Rome by Henry for the purpose of sounding Pope Clement upon the subject of the divorce. The pontiff was in a situation unfavourable to the success of the application; and although he was bound to the English monarch by the ties of gratitude, he declined giving an immediate assent to the proposition, but appointed two legates to hear and determine the validity of the first marriage of Henry. He also gave a solemn promise not to recall the commission, nor to do any act which should annul the judgment or prevent the progress of the trial. The pontiff was at this period engaged in a contest with the imperialists; but he at last concluded a treaty of alliance with the emperor, who appeared the only potentate capable of shielding him from his other enemies. The forensic disputes respecting the divorce still remained unsettled, and, from the date above mentioned, Clement took his final part against the degradation of the queen of England, who was an Austrian princess. But still, by ingenious delays and plausible formalities, he contrived to amuse Henry, whose power it was not his interest to treat with direct contempt. The patience of the English monarch, however, was now completely worn out by these fruitless attempts at negotiation, and he redoubled his entreaties to the pope to comply with his demands. Clement, in order to show a willingness to acquiesce in the wishes of Henry, sent over Cardinal Campeggio, who, either separately or in conjunction with Wolsey, was empowered to hear and determine the matrimonial suit. The legate at first attempted to dissuade Henry from pursuing the divorce; but being unsuccessful with the monarch, he next tried to persuade Catherine to embrace a religious life, in which he also failed. The popular feeling was against Henry, and he felt himself compelled to remove Anne Boleyn from court, where she had for some time resided. At a great council which he convoked, he declared that in prosecuting this matter he was solely actuated by a desire to know whether or not his only remaining child Mary was the rightful heir of the crown. On this occasion he made an appeal to the feelings and consciences of his hearers which affected them much; and the perplexities consequent upon the late proceedings afforded Campeggio an opportunity for putting off the decision of the question until he had obtained further instructions from Rome. Meanwhile Clement was seized with a dangerous illness, which retarded his answer, and is said to have revived in the ambitious mind of Wolsey a hope which he had before indulged in, of obtaining possession of the tiara. This occurred in the spring of 1529; and although the pope recovered from his sickness, his legate contrived from time to time to postpone the trial. On the 31st of May, however, the court of parliament met, and summoned the king and queen to meet on the 18th of June. The latter obeyed, but protested against the judges, and appealed to the pope. At the next session, on the refusal of the cardinals to admit the appeal, she rose, and in a calm and dignified manner threw herself at Henry's feet, imploring him in a truly eloquent address to desist from his intended purpose of repudiating her. It made a profound impression upon the audience, and even touched the cold heart of her husband. The legates carefully prolonged the trial until July, when a vacation from July to October took place, during which time all courts were bound to suspend their sittings; and, notwithstanding the importunities of the king, Campeggio contrived to get the suit removed to Rome. Agreeably to the instructions of Clement, Campeggio quitted England, and the pope summoned Henry to appear before him in forty days.

In these transactions Wolsey took no inconsiderable share, and the compliant manner in which he gave his consent to the suggestions of Campeggio excited the suspicions of the king, that his minister was playing a double game with him. The symptoms of approaching disgrace now became too palpable to escape the notice of the cardinal; for all parties joined either openly or privately to destroy him who had so long enjoyed the favour of the king. It was a singular coincidence that the friends both of Queen Catherine and Anne Boleyn were employed as instruments of his overthrow. On the 9th of October 1529 a prosecution was commenced against him for procuring bulls from Rome without the king's license. On the 17th of the same month the great seal was taken from him and given to Sir Thomas More. On the 1st of December the lords presented an address to the king, in which were embodied various articles of accusation against the cardinal; and notwithstanding that the more serious parts of the charge were refuted by his servant Thomas Cromwell, the court at last pronounced him to be beyond the protection of the law, and "that his lands, goods, and chattels were forfeited, and that his person was at the mercy of the king." Wolsey had confessed his offence against the statute of *præmunire*, of which he was technically guilty, inasmuch as he had received the bulls without a formal license. It is scarcely necessary to observe that the sentence pronounced was most unjust; for the bulls had been obtained with the consent and for the service of his ungrateful master, under whose eye they had been executed for years without a word being uttered as to the manner in which they had been obtained. But nothing could now save the cardinal. He was at once hurled from his place of pride and power, and fell, with his vast possessions, a helpless victim, into the hands of the king. But it would appear that, from habit perhaps, Henry still cherished a feeling of partiality for his old favourite, and sent him from time to time tokens of his esteem and regard. In February 1530 Wolsey was actually pardoned, and restored to his see of Winchester, and to some other emoluments. Even the great diocese of York was shortly afterwards restored; but at the moment when he was making magnificent preparations for his installation on the archiepiscopal throne, he was arrested at Cawood on a charge of high treason. His health was infirm, and during his journey from York he was seized with a dysentery, which confined him for some time at the seat of Lord Shrewsbury. As soon as he was able he mounted his mule and resumed the journey. But his strength rapidly declined, and he was compelled to take refuge in the abbey of Leicester, where he expired on the 30th of November 1530, in the sixtieth year of his age.

After the death of Wolsey, the king, by the advice of his ministers, had the legality of his marriage debated in all the universities of Europe. (See the article CRANMER.) By dint of money he succeeded in obtaining their votes in his favour, but not without a stubborn opposition. Backed by these judgments, Henry appealed to the pope; but Clement remained inflexible, and the king prepared to resist the papacy, though not yet to separate himself entirely from the church of Rome. In 1532 Cranmer was elevated to the archbishopric of Canterbury; and early in the following year Henry privately married Anne, and thus himself determined the long debated topic. A few months afterwards he openly solemnized his marriage with Anne, who went in state with him as queen. On the 23d of May Cranmer pronounced, not a divorce, but a sentence that the king's marriage with Catherine had been and was a nullity, because it had been contracted and consummated against the divine law; and not long afterwards he confirmed the marriage of the king with the Lady Anne, whose coronation was performed in the most gorgeous manner on the first of June 1533. (See BOLEYN.) The unfortunate Catherine, perceiving all further opposition to be vain, retired to Ampthill, near Dunstable, where she remained for the rest of her days in privacy and peace.

The pope was no sooner informed of these proceedings, than he passed a sentence declaring Catherine to be the king's only lawful wife; requiring him to take her again, and denouncing censures against him in the event of refusal. Henry, on the other hand, knowing that his subjects were entirely at his command, resolved to separate altogether from the church of Rome. In the year 1534 he was declared head of the church by parliament; the authority of the pope was completely abolished in England; all tributes formerly payable to the holy see were declared illegal; and the king was intrusted with the collation to all ecclesiastical benefices. The nation readily entered into the king's measures, and took an oath called the *oath of supremacy;* all the authority which the popes had maintained over England for ages was overthrown at a blow; and none seemed to repine at the change except those who, from their dependence upon Rome, were immediately interested.

But though the king thus separated from the church of Rome, he by no means adhered to the doctrines of Luther which had been lately promulgated. He had himself written a book against this celebrated reformer, which the pope pretended greatly to admire, and honoured King Henry, on this account, with the title of Defender of the Faith. This character he seemed to be determined to maintain, and therefore persecuted the reformers most violently. Many were burnt for denying the Catholic doctrines, and some also were executed for maintaining the supremacy of the pope. The courtiers knew not which side to take, both the new and old religions being equally persecuted; and as both parties equally courted the favour of the king, he was by that means enabled to assume an absolute authority over the nation.

The established clergy co-operated actively in the revolution which was in progress. Six bishops sanctioned by their vote every blow which was struck at the power of Rome; and fourteen abbots were usually present when the number of temporal peers who attended were somewhat more than forty. "They did not shrink," says Sir James Mackintosh, "from the deposition of Catherine, by reducing her title to that of Princess Dowager of Wales. By ratifying the marriage of Anne Boleyn they adopted those parts of the king's conduct which most disgusted the people. The bill for subjecting the clergy to the king, as their sole head, was so favourably treated as in one day to be read three times and passed: no division appears to have taken place on these measures."[1]

The attention of the king was now turned to Elizabeth Boston, a nun in the priory of St Sepulchre at Canterbury, who believed herself endowed with the power of working miracles, and foretelling future events. Several clergymen and other gentlemen of Kent believed in her mission; and some individuals of the highest order, both of intellect and piety, gave credit to her pretensions. She was subject to convulsions; and in the trances into which she frequently fell, visions of a marvellous nature were vouchsafed to her, which turned of course upon the extraordinary events taking place around her. She was tried and executed for high treason, and her abettors were arraigned on the same charge. Fisher, bishop of Rochester, was attainted by the act against this modern Pythia; but by a separate statute he was afterwards attainted of misprision of treason, for not having taken the oath to the succession. He was eminent for his learning and virtue, and probably his life would have been saved had not the pope sent him a cardinal's hat while in prison, which roused the jealousy of Henry. The remorseless tyrant ordered him to be executed, at the same time remarking, with his usual heartlessness, that the pope might send him a hat, but that Fisher should have no head to wear it. Another deed of blood was perpetrated a short time afterwards, which alone is calculated to consign the name of Henry VIII. to the execration of all future times. Sir Thomas More, the first Englishman of his day, one who had exalted the nation in the eyes of Europe, and whose fame was universal, was tried and executed for misprision of treason, in not taking the oath to maintain the succession. The legal pretext, if there was any, for the accusation, was grounded on the obnoxious clause of a recent act, which made it treason "to do any thing by writing or act which was to the slander, disturbance, or prejudice of the marriage with the Lady Anne, or to the disherison or disturbance of the king's heirs by her." Both More and

---

[1] *History of England*, vol. ii. p. 175.

Fisher had abstained from either affirming or denying, first, that Henry's marriage with Catherine was invalid; secondly, that his marriage with Anne was valid; and, thirdly, they refused to disclaim all foreign authority in the kingdom, spiritual authority included. After his condemnation Sir Thomas avowed that he had studied the question for seven years, and could not escape from the conclusion that the king's marriage with Catherine was valid. For this scrupulous conscientiousness he expired upon the scaffold on the 7th of July 1535.

This wanton shedding of righteous blood excited the utmost indignation in foreign countries, particularly in Italy. Here Giovio, an historian, compared the tyranny of Henry to that almost preternatural wickedness which the Grecian legends had embodied under the appellation of Phalaris. Other individuals lashed the tyranny of the English monarch with the utmost rigour, and lamented, in strains of affecting eloquence, the fate of More, whom they designated the martyr of unshaken probity. Amongst the most eminent of these writers was Cardinal Pole, an Englishman, allied to the royal family.

Catherine, the former consort of Henry, expired at Kimbolton in the beginning of January 1536, having died as she had lived, mild, forgiving, and resigned. On her deathbed she wrote a most affectionate letter to her husband, whose iron nerves were touched by the perusal of it. His less prudent queen had the levity to express her satisfaction at the event. But if she expected that it would in any way be conducive to her further happiness, and a more devoted attachment on the part of her husband, she was most miserably disappointed. She soon after gave birth to a still-born child, and her brutal lord is said to have reproached her upon the occasion for the loss of his boy. His desire for male issue, and his repeated disappointments, seem to have at last weaned the affections of the fickle monarch from the idol whom he had worshipped with so much devotedness and ardour. A new passion had kindled in his breast, the object of which was Jane Seymour, a young lady of the queen's bed-chamber, which office Anne herself had held in that of Catherine. The circumstances connected with the queen's arrest may be briefly stated. On May-day 1536 a tilting match was held at Greenwich, in which her brother was the chief challenger, and Norris, groom of the stole, the opposing defendant. The queen having dropped her handkerchief, had it gallantly handed up to her by Norris, who was supposed to be her lover. The jealousy of the king burst out; he left the joust precipitately; and ere night his queen had passed through an examination, and was committed a prisoner. Such was the trifle "light as air," which to the jealous mind of Henry seemed a "confirmation strong as proofs of holy writ." By the researches of Mr Turner it has been discovered, that some days before the tournament certain individuals were appointed to inquire into the alleged misdeeds of Anne. The commission put their authority into execution upon the 10th of May, when a grand jury of Westminster was assembled. The charge against her was adultery, and its consequence in such a case, treason. Whether innocent or not, the unhappy Anne was deserted in her utmost need, and had not a friend to counsel her in this alarming emergency. On the day after the queen was committed to the Tower, Cranmer had written to the king imploring the king's mercy towards her, "his life so late, and sole delight;" but in vain. The archbishop had been forbidden to approach the court until desired by the king. The subsequent proceedings were as rapid as they were terrible. On the 12th of May, Norris, Weston, Brereton, and Smeaton, were tried in Westminster Hall for the crime of high treason. Smeaton pleaded guilty to the charge; the others resisted, but were convicted. Three days afterwards the House of Lords assembled for the trial of the queen. She was without counsel, and attended only by her ladies. Anne defended herself with modesty and firmness, but, upon evidence of which no traces now remain, she was condemned to suffer death. On hearing the sentence of her judges, she raised up her hands and exclaimed, "O Father and Creator! O thou who art the way, the truth, and the life! thou knowest that I have not deserved this death." It is difficult to reconcile such an ejaculation with a consciousness of guilt. She afterwards turned to her judges, and made a serious protestation of her innocence. On the 17th of May the other individuals who had been convicted were carried forth to execution. Smeaton, who had confessed to the guilt, probably from an erroneous impression that he would by this means save his life, was the last to suffer. Anne's brother Rochford was also tried and condemned on the same day with herself, and was executed with the others. The curtain dropped upon this horrible tragedy with the death of the queen, who was beheaded on the day after her supposed accomplices had suffered. For further particulars respecting this unhappy personage, see Boleyn.

That Henry sacrificed his queen in a fit of vindictive resentment against her, who, he too rashly believed, had dishonoured him, is all that can be urged in his favour. That he really believed her guilty, must also in common fairness be allowed. To think otherwise would be to attaint his name with one of the most horrid enormities that ever disgraced the annals of crime. It seems very improbable that the violent attachment which he had all along entertained for her should have cooled so suddenly, and been supplanted by such deadly hate, without supposing that some levities in the conduct of Queen Anne had fired his jealous soul, and roused him to demand her blood as an expiation for the guilt imputed to her. But he was not content with taking away her life under the charge of adultery and incest; he deprived her of the name and the right of wife and queen, and bastardized the daughter which she had born him, even when he acknowledged that daughter to be his own. His contempt for her memory was displayed in a manner which could be believed of few other individuals. He dressed himself in white on the day of her execution, and actually married Jane Seymour next morning.

In bringing this tale of blood to a termination, we have unavoidably outrun several important events. When the news of Sir Thomas More's execution reached the court of Rome, a bull was prepared against Henry. In this extraordinary instrument were embodied all the offences of the English monarch against the papal see, and he was allowed ninety days, and his fautors and abettors sixty, to repent, and to appear at Rome either in person or by attorney. In case of default, he was to be excommunicated, and deprived of his crown; his children by Anne were to be rendered incapable of inheriting for several generations; his subjects were to be absolved from their allegiance to him; and all treaties and alliances between him and other powers were to be null and void. This thunderbolt, however, though forged for the purpose of punishing the king's apostacy, it was resolved should be suppressed for a time, and lodged in the papal armoury until a more favourable opportunity should occur for launching it at the royal culprit.[1] The election of Henry as supreme head of the church we have already noticed, and also some of the events which followed his assumption of that presumptuous title. Henry, however, at first assumed it with wariness, and the language in which the statute is couched shows that his supremacy might be reconciled with the papal authority, if the jurisdiction of that power were only of a spiritual nature. But by the statutes of later years, the revolution in church government had been consummated in England. The ancient doctrine of the Roman Catholic faith was acknowledged; but the king was placed as a sort of lay patriarch at the head of the ecclesiastical establishment. Thomas Cromwell, who had now become Henry's chief minister (see CROMWELL, THOMAS), was at this time raised to the new office of the king's vicegerent, and empowered to send commissioners into the several counties of England to inspect the monasteries, and to report, with rigorous exactness, the conduct and deportment of such as were found there. This appointment, which had been made between the parliaments of 1536 and 1539, was confirmed by the recognition of the latter; and it was provided that the vicegerent should take his seat in the House of Peers before the Archbishop of Canterbury, and be ranked above all temporal lords, except some branches of the royal family. The first experiment which Cromwell made of his unlimited power was the gradual suppression of the various classes of religious houses, and the seizure of their possessions, at that time amounting to a large proportion of the landed property of the kingdom. This seizure of vested territorial possessions was, in a legal point of view, direct spoliation. But it was urged, on the other hand, that from the immorality, ignorance, and indolence in which those who enjoyed them indulged, they had forfeited their right, and might lawfully be deprived of these. By the inspectors of the religious houses, the public were informed of the existence of monstrous disorders in these communities. In 1536 the lesser monasteries were suppressed, amounting to nearly four hundred. Their revenues, computed at L.30,000 per annum, were confiscated to the king's use, besides their plate and other goods, estimated at L.100,000 more. The confiscation, however, was most unpopular, especially in those places where the ancient faith retained most sway, and occasional revolts broke out. Such a sweeping calamity must have brought ruin upon many innocent and even worthy and deserving persons. The spectacle of individuals, invested with the most sacred of all functions, expelled from their only habitations, where they had probably grown old, and were now unfit for bodily toil, was calculated to awaken feelings of sympathy for the sufferers, and probably of detestation for those who had driven them forth to perish in the wilderness. A disturbance broke out in Lincolnshire, where the first visitation of religious houses took place. But in the north a more serious affair, amounting to an insurrection, occurred. Between the Humber and the Tweed the people had rushed to arms, and they were joined by the inhabitants of Cumberland, Westmoreland, and a portion of Lancashire. This formidable body was led into the field by Robert Ask, a man of Yorkshire, and was preceded by priests bearing banners emblazoned with paintings of the sufferings of Christ. Several important towns fell into their hands; but the king met them with a superior force, which arrested their progress. They, however, succeeded in obtaining a general pardon, and then dispersed.

---

[1] Thus far historians are perfectly agreed with regard to this bull. It is also certain, that in 1538 the suspension of the bull was revoked, and its publication ordered by the pope. But whether or not this really took place is a matter of doubt. Dr Lingard ob-

A second visitation of the monasteries took place shortly afterwards. Various circumstances had occurred to exasperate Henry against the Catholic clergy; and the alarming revolts, at which priests had presided, and principally instigated the people by their inflammatory addresses, were of a nature to inflame such a combustible temper as his. In this second spoliation, the richest and most revered shrines were pillaged and destroyed, and the sacred relics, objects of so much superstitious veneration, were held up to the derision of the public. Various historians have enumerated a great number of these, and some of them are certainly calculated to excite surprise at the depth of that superstitious feeling which could induce a people to believe that the parings of St Edmund's toes, or the felt of St Thomas of Lancaster, or the shirt of St Thomas of Canterbury, were infallible recipes for certain disorders. On this occasion the shrine of the latter saint was demolished, and the wealth which it yielded was enormous. These shrines were pillaged, on the allegation, too often true, that they were the scenes of imposture, where miracles were pretended to be wrought. The king, on the whole, suppressed upwards of six hundred monasteries, above two thousand chantries and free chapels, and about two hundred colleges and hospitals. The confiscation was closed by a statute passed in 1539, which provided that "all monasteries, and other religious houses, dissolved, suppressed, surrendered, renounced, relinquished, forfeited, or by any means come to his highness, shall be vested in him, his heirs and successors, for ever." It must be owned, that although great abuses may have been detected, revenue not reformation, plunder not punishment, were the objects which the visitors had in view. With respect to the important question regarding property, involved in this measure, we shall avail ourselves of the remarks of Sir James Mackintosh on the subject.

"Thus was completed the confiscation of a fifth or a fourth part of the landed property of England and Wales within the space of five years. It may be a fit moment therefore to pause here, in order calmly and shortly to review some of the weighty questions which were involved in this measure. There is no need of animadverting upon the means by which it was effected, though we must assent to the affirmation of a great man, 'that an end which has no means but such as are bad, is a bad end.' But the general question may be best considered, keeping out of view any of those attendant misdeeds which excite a very honest indignation, but which disturb the operation of the judgment. Property is legal possession. Whoever exercises a certain portion of power over any outward thing in a manner which, by the laws of the country, entitles him to an exclusive enjoyment of it, is deemed a proprietor. But property, which is generally deemed to be the incentive to industry, the guardian of order, the preserver of internal quiet, the channel of friendly intercourse between men and nations, and, in a higher point of view, as affording leisure for the pursuit of knowledge, means for the exercise of generosity, occasions for the returns of gratitude; as being one of the ties which join succeeding generations, strengthening domestic discipline, and keeping up the affections of the kindred; above all, because it is the principle to which all men adapt their plans of life, and on the faith of whose permanency every human action is performed; is an institution of so high and transcendent a nature, that every government which does not

---

serves, "I cannot find any proof that it was ever published at all." Sir James Mackintosh is silent upon the point. Mr Turner, in his *History of the Reign of Henry VIII.* says, that in 1538 "it was given unblushingly to the world. This last order recites, that it had been suspended for three years on the persuasion of some princes. Cherubini, 623." In order to reconcile these conflicting statements, it may perhaps be supposed that it never was "published at all" in England, although it may have been "given unblushingly to the world" in other countries.

protect it, nay, that does not rigorously punish its infraction, must be guilty of a violation of the first duties of just rulers. The common feelings of human nature have applied to it the epithets of sacred and inviolable. Property varies in the extent of the powers which it confers, according to the various laws of different states. Its duration, its descent, its acquisition, its alienation, depend solely upon these laws. But all laws consider what is held or transmitted agreeably to their rules as alike possessing the character of inviolable sacredness. There may be, and there is, property for a term of years, for life, or for ever. It may be absolute as to the exercise of the proprietor's rights, or it may be conditional, or, in other words, held only as long as certain conditions are performed. There are specimens of all these sorts of property in the codes of most civilized nations. But in all these cases the essence of property is preserved, which consists in such a share or kind of power as the laws confer. The advantages may be extremely unequal. The inviolable right must, by the force of the terms, continue perfectly equal.

"The legal limits of the authority of the supreme legislature are not a reasonable object of inquiry, nor indeed an intelligible form of expression. But to conclude that, because the law may in some cases be said to create property, the law is to be deemed on that account as entitled rightfully to take it away, is a proposition founded on a gross confusion of two very distinguishable conceptions. It uses the word property in the premises for a system of rules, and in the conclusion for a portion of external nature, of which the dominion is acquired by the observance of these rules. It is only in the first of these senses that property can be truly called the creature of law. In the second sense it is acquired or transmitted, not by law, but by the acts of a man, when the acts are conformable to legal rules. It is impossible within our present limits to canvass the small or apparent objections which may occur to this scheme of reasoning. It is sufficient, perhaps, here to remark, that these are the generally acknowledged principles, and that deviations from them in practice are no more than partial irregularities, to which the disturbing forces of passion and interest expose human society.

"The clergy, though for brevity sometimes called a corporation, were rather an order in the state composed of many corporations. Their share of the national wealth was immense, consisting of land devised by pious men, and of a tenth part of the produce of the soil set apart by the customary law of Europe, for the support of the parochial clergy. Each clergyman had only in this case an estate for life, to which, during its continuance, the essential attribute of inviolable possession was as firmly annexed by law as if it had been perpetual. The corporate body was supposed to endure till it was abolished in some of the forms previously and specially provided for by law.

"For one case, however, of considerable perplexity there was neither law nor precedent to light the way. Whenever the supreme power deemed itself bound to change the established church, or even materially to alter the distribution of its revenues, a question necessarily arose concerning the moral boundaries of legislative authority in such cases. It was not, indeed, about a legal boundary; for no specific limit can be assigned to its right of exacting obedience within the national territory. The question was, what governments could do morally and righteously, what it is right for them to do, and what they would be enjoined to do hy a just superior, if such a personage could be found among their fellow-men. At first it may seem that the lands should be restored to the heirs of the original grantor. But no provision for such a reversion was made in the grant; no expectation of its occurrence was entertained by their descendants; no habit or plan of life had been formed on the probability of it. The grantors or founders had left their property to certain bodies under the guardian power of the commonwealth, without the reserve of any remainder to those who, after the lapse of centuries, might prove themselves to be their representatives. It is a case not very dissimilar to that of an individual who died without discoverable heirs, and whose property for that reason falls to the state. It appeared, therefore, meet and righteous that in this new case, after the expiration of the estates for life, the property granted for a purpose no longer deemed good or the best, should be applied by the legislature to other purposes which they considered as better. But the sacredness of the life estates is an essential condition of the justice of such measures. No man thinks an annuity for life less inviolable during his life, than a portion of land granted to him and to his heirs for ever. That estate might, indeed, be forfeited by a misperformance of duty; but perfect good faith is in such a case more indispensahle than in most others. Fraud can convey no title; false pretences justify no acts. There were gross abuses in the monasteries; but it was not for their offences that the monastic communities fell. The most commendable application of their revenues would have been to purposes as like those for which they were granted as the changes in religious opinion would allow. These were religious instruction and learned education. Some faint efforts were made to apply part to the foundation of new bishoprics; but this was only to cover the profusion with which the produce of rapine was lavished on courtiers and noblemen, to purchase their support of the confiscations, and to ensure their zeal and that of their descendants against the restoration of popery.

"It is a melancholy truth, and may be considered by some as a considerable objection to the principles which have been thus shortly expounded, that if in 'the seizure of abbey lands' the life estates had been spared, the monks, who were the main stay of papal despotism, and the most deadly foes of all reform, would have had arms in their hands which might have rendered them irresistible. It must perhaps be acknowledged, that it was more necessary to the security of Henry's partial reformation to strip the monasteries at that moment, than to dissolve communities which a better regulation might in future reconcile to the new system.

"We are assured by Sir Thomas More, 'that in all the time while he was conversant with the court, of all the nobility of this land he found no more than seven that thought it right or reasonable to take away their possessions from the clergy.' So inconsiderable was the original number of those who, not many years after, accomplished an immense revolution in property.

"To which it must be answered, that the observance of justice is more necessary than security for any institution; that many regulations might have stood instead of one deed of rapine; that the milder expedients would have provoked fewer and more reconcilable enemies; that if, on the whole, they afford less security, the legislature were at least bound to try all means before they who were appointed to be the guardians of right set the example of so great a wrong. Rulers can never render so lasting a service to a people as by the example, in a time of danger, of justice to formidable enemies, and of mercy to obnoxious delinquents. These are glorious examples, for which much is to be hazarded."

Henry had now so far separated himself from the communion of Rome, that it became in some measure necessary for him to concoct a creed of his own. The clergy were divided into two factions, denominated the men of the old and the new learning. The chief of the former was Gardiner bishop of Winchester, who was supported by Lee archbishop of York; Stokesly bishop of London, Tunstall of Durham, and Clarke of Bath and Wells. The latter acknowledged as leaders, Cranmer archbishop of Canterbury, Haxton of Sarum, Latimer of Worcester, and Fox of Hereford. These could depend on the powerful interest of Cromwell the vicar-general, and of Audley the lord chancellor; those on that of the duke of Norfolk, and of Wriothesley the premier-secretary. Various long debates took place upon the new creed, but it was neither completed nor sufficiently fenced round with suitable penalties, till an act was passed by the parliament, which sat in April 1539, entitled "an act for abolishing diversity of opinions." This convocation was opened by the chancellor informing the House of Lords that it was his majesty's earnest desire to extirpate from his kingdom all diversity of opinions with regard to religion; and as this enterprise was, he owned, difficult and important, he desired them to choose a committee from amongst themselves, who might frame certain articles, and communicate these afterwards to parliament. The lords named the vicar-general Cromwell, now created a peer; the Archbishops of Canterbury and York; and the Bishops of Durham, Carlisle, Worcester, Bath and Wells, Bangor, and Ely. But this small committee itself was agitated with such diversity of opinions that it could come to no conclusion. The Duke of Norfolk then moved, that since there was no hope of having a report from the committee, the articles of faith proposed to be established should be reduced to six, and a new committee be appointed to frame an act respecting them. As this peer was understood to speak the king's mind, his motion was immediately complied with; and, after a short prorogation, the bill of the six articles was introduced, and, having passed the two houses, received the king's assent. By this law the doctrine of the real presence was established, the communion in one kind, the perpetual obligation of vows of chastity, the utility of private masses, the celibacy of the clergy, and, lastly, the necessity of auricular confession. The denial of the real presence was punishable with death by fire, and the same forfeiture as in cases of treason, and admitted not the privilege of abjuring; an unheard of cruelty, unknown even to the inquisition itself. The denial of any of the other articles, even though afterwards recanted, was punishable by the forfeiture of goods and chattels, and imprisonment during the king's pleasure. An obstinate adherence to error, or a relapse, was adjudged to be felony, and subjected the delinquent to death. The marriage of priests was punished in the same manner. Their commerce with women was, for the first offence, forfeiture and imprisonment; and for the second, death. Abstaining from confession, and from receiving the eucharist at the accustomed times, subjected the person to fine, and to imprisonment during the king's pleasure; and if the criminal persevered after conviction, he was to suffer death and forfeiture, as in cases of felony. Commissioners were to be appointed by the king for inquiring into these heresies and irregular practices, and the criminals were to be tried by a jury.

Henry had now been a widower for above two years. In 1537 Jane Seymour, his third queen, had born him a son, afterwards Edward VI.; but she herself expired in less than a fortnight afterwards. The king afterwards made proposals of marriage to several foreign princesses, and others, without success. Under these repeated disappointments, he readily listened to the suggestions of Cromwell, who proposed to him Anne, sister of the Duke of Cleves, a considerable prince on the Lower Rhine, who had lately established Lutheranism in his principality. This choice showed the leaning of his secretary's mind, and the progress of men in general towards reformation. Henry had seen a painting by Holbein of this lady. The artist had invested her with fictitious charms, which captivated the sensual monarch, and inspired him with such eagerness to behold her, that he proceeded to Dover, where she was to disembark, his mind no doubt swelling with pleasing anticipations. But he was miserably disappointed, and could not conceal his chagrin. She was indeed of the standard dimensions, being large and tall as his heart could desire; for stature had now become an indispensable qualification in the individual who should aspire to gain the affections of the king of England. Without entering into the disgusting particulars connected with his marriage with Anne of Cleves, it is sufficient to state that the nuptials were solemnized, and that the lady was treated, not as a wife, but as a friend. The distress of Henry was great, and at last drew the attention of the House of Lords to the subject on the 6th of July 1540. These obsequious peers entreated him to make inquiry into the validity of his marriage with the Lady Anne of Cleves; and the Commons having concurred with them, the king granted their prayer. Of course this drama was all arranged, and the characters cast, some days before the meeting of parliament. The convocation appointed to examine into the matter declared the marriage to be null by the consent of Lady Anne herself, which was insured by the grant of an income of L.3000 annually; and the lady, it would appear, lived comfortably on her annuity for sixteen years in England. The bill for the nullity was passed by both houses, and received the royal assent on the 24th of July 1540. About a fortnight afterwards the king married his fourth wife, Catherine Howard, niece to the Duke of Norfolk. But let us look back upon the fate of Cromwell, who was instrumental in procuring the former union. It was indispensably necessary that the revolutions which took place in Henry VIII.'s palace and bed should in some way or another be marked with blood.

The arrest, condemnation, and execution of Cromwell, is another of those cruel and tyrannical measures which have entailed accumulated odium upon the name of Henry VIII. A bill to attaint the vicar-general of high treason was brought into parliament in June 1540; and before the end of the month it had passed through both houses. He was charged with heresy because he had favoured the new doctrines, and with treason because he had performed several acts of royal authority without the warrant of the king. Cromwell was condemned unheard, and executed in about a month afterwards. This was an act of gross injustice, but it was far from being unpopular. The nobility were glad to be rid of an individual who had raised himself from the shop of a fuller to the highest offices of state; and the Roman Catholic party, who were the most numerous, and had regained much of their ascendency, rejoiced at the fall of one who was the active conductor of that system of confiscation which struck such a blow at their power in England. In that business he certainly must have connived at much rapine and robbery, which it was out of his power to prevent. He has also been charged with Machiavelian policy; but there is no satisfactory evidence that he was unfaithful to his sovereign. Like Wolsey, he seems to have served his king more faithfully than his God; and it is remarkable that he fell into his own snare, having repeatedly shown the example of attainder without trial.

At this period the act of the six articles was in the fullest vigour of its cruelty; and many iniquitous executions took place. One of the most horrid of these was that of Courtney marquis of Exeter, with Lord Montague and Sir Edward Nevil. They were descended from Edward IV., and this seems to have constituted their only crime. Towards the close of 1538 they were first arrested and committed to the Tower; and shortly afterwards the Countess Margaret, the mother of the Poles, was also taken into custody. Exeter was charged with the offence of having conspired to raise Reginald Pole to the throne. This individual, best known as a cardinal, was the son of the above-named lady, who was daughter of the Duke of Clarence. Her son's life was principally passed in Italy, where he was much celebrated for his talents; and Henry appears to have been proud of him, for he munificently discharged his expenses. Their friendship, however, terminated with the king's divorce from Catherine, which the English monarch vainly besought Pole to sanction. The revenge of Henry, who seems now to have thought that without the shedding of blood there could be no remission of offences, fell upon the mother of the cardinal, and the last of the Plantagenets. She was attainted of high treason, and sent to prison, as above noticed. The noblemen committed about the same time were soon afterwards executed; but the lady lingered two years in confinement, and was at last conducted to the scaffold on the 27th of May 1541, where, to complete the horror of the transaction, from mismanagement on the part of the executioner, her neck was horribly mangled, and her grey hairs, clotted with blood, fell dishevelled over her face ere the bloody act was consummated.

To return to the domestic affairs of Henry, he had not been many months married to Catherine Howard before he received such information of her dissolute life before marriage as induced him to suspect that she might still continue it, and to cause a rigid inquiry to be made into her conduct. There was no doubt as to her vices previously to her union with the king; and some acts of infidelity after it were also brought home to her, but the details are too disgusting for human feelings. Cranmer was one of the individuals employed to communicate information to the king; and although there is no evidence that he was ever guilty of a malicious or vindictive act, yet he sometimes wanted the courage to resist crimes; and the slavish manner in which he, along with the rest of the ministers and parliament in general, bowed to the despotic will of the king, cannot be extenuated.

Two of Catherine's paramours were arrested, and confessed their crimes; and the queen herself acknowledged her guilt previously to the marriage, but denied having committed any act of infidelity subsequently thereto. This, however, was not believed; and on the 14th of February 1542 she was executed in the Tower, along with Lady Rochford, who in some way or another was implicated as an accomplice in the guilt of the queen.

To attaint without trial had now become fashionable; but to punish with death that which was not made criminal by any former statute, was altogether new. To countenance such severities as those which had lately taken place, it was enacted in the very bill of attainder, that every woman about to be married to the king or his successors, not being a maid, should disclose her unchastity to him, under the penalty of treason; that any person knowing the fact and not disclosing it, should be subject to the lesser penalty of misprision of treason; and that the commission of adultery by the queen or wife of the prince should be punishable with death.

These laws afforded some amusement to the people, who now said that the king must look out for a widow, as no reputed maid would be disposed to offer herself whilst such a dreadful statute was suspended over her head. This in reality took place, for on the 10th of July 1543 Henry espoused Catherine Parr, the widow of Lord Latimer, and a lady of mature age. She had read Lutheran books, and was inclined to support the doctrines of the reformers. She even went so far as to enter into controversy with her imperious lord, who valued himself not a little on his theological knowledge. He ordered Wriothesley and Gardiner to give orders for her imprisonment, and to prepare articles of impeachment against her. The third Catherine had very nearly been honoured with a place upon the list of victims which were sacrificed by this Blue Beard of the west, but she evaded the blow by her ingenuity and tact. During the remainder of her life, however, she never again ventured to provoke the vengeance of the royal polemic.

As head of the church, the attention of the king was now principally turned to the management of its affairs. He enforced an observance of the six articles both by Protestants and Catholics, and any deviation from them was punished with tyrannical severity. He was very impartial in his distribution of what he called justice; and it was not uncommon for individuals professing opposite faiths to perish at the same stake. The Christian of those days had a difficult part to perform; for whilst the king renounced in one respeect the authority of the pope, he acknowledged it in another by his adherence to the doctrines of the church of Rome; so that it frequently happened that those who were against the head of it were burned, and those who were for him were hanged. In connection with church affairs, Henry effected a further dissolution of colleges, hospitals, and other foundations of that nature, with the spoils of which he enriched his treasury. He also extorted from many bishops a surrender of their chapter lands, and in this manner he succeeded in pillaging the sees of Canterbury, of York, and of London. Amongst the religious orders suppressed was that of the Knights of Malta, or, more properly, St John of Jerusalem. They obstinately refused to surrender along with the other monasteries who laid their rights at the feet of the king, and he was compelled to have recourse to parliament for the purpose of obtaining its authority for dissolving the order, which was very rich, and whose spoil was therefore precious in his sight.

For the purpose of maintaining a rigid purity in speculative principles, he nominated a commission of divines to make out a creed for the benefit of his subjects. In connection with this appointment a circumstance occurred which strongly marks the character of this reign, as well as of those who composed the council of the nation. Before the reverend conclave had made any progress in its arduous undertaking, the parliament passed a law which went to ratify all the tenets which the divines might establish in accordance with the king's consent. This clearly shows that the individuals composing that body, as well as the parliament, were merely ciphers, and that Henry was the initial unit which gave them value. A small volume was published under the title of *The Institution of a Christian Man*, which was made the infallible standard of orthodoxy. But the king's inconsistency was as strikingly exemplified in his religion as in his morals. A new book was ordered to be composed, and three years were spent before it could be brought to that desirable state of perfection which the king wished. At length, however, it came forth under the title of *A necessary Doctrine and Erudition for any Christened Man*; and in order to distinguish it from the former work upon the same subject, it was called emphatically the king's book. It taught the same doctrines as the preceding compilation, with the addition of transubstantiation and the sufficiency of communion under one kind. The new creed was generally approved of, and all writings in opposition to it were prohibited. From the period of the publication of the "king's book" until the accession of the next sovereign, it continued to be the only authorized standard of English orthodoxy. Henry had formerly sanctioned the publication of the Bible in English, and permission was granted to all his subjects to peruse it. But he afterwards retracted the liberty which he had vouchsafed them, and prohibited the reading of the Scriptures by the lower orders of the people under the penalty of imprisonment. The mass book was also examined, and some alterations were made upon it.

But to return to the political affairs of the nation; in the beginning of the year 1543 Henry renewed his friendship with the emperor, which had been suspended by the divorce question. They concluded an alliance against Francis; and on the 14th of July 1544 Henry crossed the seas in a ship furnished with sails of cloth of gold. The principal event of this war was the surrender of Boulogne, into which the English monarch made a triumphant entry on the 18th of September. But he shortly afterwards returned to England. On the 7th of June 1546 hostilities were concluded by a treaty, of which the principal stipulation was, that within eight years Henry should receive two millions of crowns, with arrears and costs, which are enumerated; and, on payment of these sums, Boulogne and its dependencies were to be restored to Francis. Henry's warlike propensities were also exercised in reference to Scotland and Ireland; but peace was finally restored after both countries had suffered considerably, especially the former. These wars, however, exhausted the treasury of the English monarch. He was compelled to extort money from parliament in his usual manner, and also to depreciate the coinage of the realm, which he had not scrupled to do before.

The cruelty of Henry continued conspicuous to the very close of his life. Disease made dreadful ravages upon his worn-out and unwieldy frame, so that he had to be moved from place to place by machines contrived for the purpose; yet even these unequivocal tokens of approaching dissolution had no effect in subduing the vindictive spirit or humanising the mind of the sufferer. It was in this pitiable state that he perpetrated an act which has become memorable from the fame of the illustrious victim. This was the execution of Henry Howard, earl of Surrey, so justly renowned for his poetical genius. There had for some time existed a spirit of rivalry between the Seymours and the house of Howard. The Duke of Norfolk was indignant at the ascendency of the former in the royal favour; and his son, the Earl of Surrey, could not forgive the Earl of Hertford, a member of the other family, for having superseded him in the command of the garrison of Boulogne; he had also been heard to predicate that the time of revenge was not far distant. The house of Howard alone stood in the way of the Seymours in the pursuit of their aggrandisement under the approaching minority; and they accordingly employed every means of drawing down the vengeance of the king upon their heads. Norfolk and Surrey were accordingly committed to the Tower on the 12th of December 1546. Surrey was tried on the 13th of January following, on a charge of having quartered on his shield the arms of Edward the Confessor. He vainly defended himself with his usual eloquence and spirit, and showed that he had worn the arms fourteen years without giving offence, and that they had been assigned to him by a decision of the heralds. But the fact being admitted, it was taken as sufficient evidence that he aspired to the throne, and the jury condemned him to suffer death. About a week after the sentence was pronounced, this gallant and accomplished nobleman expired upon the scaffold. His father was also tried and condemned to perish in the same manner on the 29th of January. But on the morning of the 28th the spirit of Henry VIII. followed that of Surrey to the judgment-seat; and Norfolk, after remaining in prison for several years, was at length set at liberty.

Henry VIII. is one of the most repulsive sovereigns to be met with in the list of English kings. There is a gross brutality about the man, and a remorseless tyranny and blood-thirstiness about the king, which totally obscure any human features which his character may have possessed. Some of his crimes are of so dark a dye, and so peculiarly diabolical, as to make the mind shudder at the very mention of his name. It is difficult to extend charity to, or rank with ordinary humanity, one who could repeatedly hurry from his arms to the scaffold those whom he had loved and embraced with passionate tenderness, if such language may be used in reference to any feeling which animated the breast of such a barbarian. It was after the fall of Wolsey that the prominent features of Henry's moral deformity fully developed themselves; and they are such as have attached to his name a degradation which can neither be removed nor palliated. For the good which he was the means of doing, in sanctioning a reformation in the affairs of the church, he deserves no credit; for it originated in a spirit of vindictive revenge, and was perpetuated by plunder and cruelty. Henry was not destitute of ability; and the esteem which we may infer he entertained for literature, since he patronised learning, is one of the few traits of his character which are not repulsive and odious.

Henry was succeeded by his only son Edward, a boy of nine years of age. He was proclaimed king of England on the 31st of January 1547, and crowned in the month following. The most remarkable transactions of his reign are those connected with religion. The restraint which Henry VIII. had laid upon the Protestants was now taken off; and they not only maintained their doctrines openly, but soon became the prevailing party. Henry had fixed the majority of his son at eighteen years of age; and, in the mean time, appointed sixteen executors of his will, to whom, during the minority, he entrusted the government of the king and kingdom. But the first act of the executors was to choose the Earl of Hertford, afterwards Duke of Somerset, protector of the realm; and in him was lodged all the regal power, together with a privilege of naming his own privy council.

The Duke of Somerset had long been numbered amongst the secret partisans of the reformers; and, immediately on his elevation to his high dignity, he began to express his intention of reforming the abuses of the ancient religion. Under his direction and that of Cranmer, therefore, the reformation was vigorously carried forward; persecutions under the act of the six articles ceased, prisoners were released, and exiles were recalled. Homilies were composed by Cranmer, and ordered to be read by parish priests to their congregations. Visitors were appointed to inspect ecclesiastical establishments, and see that four sermons were yearly preached against the papal authority; that the worship of images should be denounced, and those who were the objects of pilgrimages and offerings should be destroyed; that the English Bible, with Erasmus's commentary on the gospels, should be placed in every church for the use of the people; together with many other points, which, without being very important in themselves, were calculated to assure the people that the government was no longer neutral in matters of religion. The principal person who opposed these innovations was Gardiner bishop of Winchester; a man of great learning, abilities, and resolution, but one of Henry's devoted agents in the suit for a divorce from Catherine, his first queen. He made a manly and becoming resistance to these injunctions, from principles of civil liberty, as much as of ecclesiastical discipline. To the disgrace of their own principles, the reformers now displayed as virulent a spirit of persecution as the Catholics had formerly done. Gardiner was committed to the Fleet prison, where he was treated with great severity. He was afterwards sent to the Tower; and having continued there two years, he was commanded to subscribe several articles, amongst which was one confessing the justice of his own imprisonment. To all the articles but this he agreed to subscribe; but that did not give satisfaction. He was then committed to close custody; his books and papers were seized; all company was denied him; and he was not even permitted the use of writing materials. Bonner of London, more violent and more subservient, escaped protracted imprisonment by obsequious submission. Several bishops also screened themselves by sacrificing a considerable share of their revenues; others were deprived of their offices; and Tunstal bishop of Durham, an eminent prelate, was ejected from the privy council, in order to impress on the people by a strong example the disinclination of the protector to the ancient faith. In November 1547 a parliament was assembled, in which several bills were passed to promote and enlarge the reformation. The communion was appointed to be received in both kinds by the laity as well as by the clergy, without condemning the usages of other churches. Bishops were to be nominated by the king, and process was to run in the king's name in ecclesiastical courts. The statutes against the Lollards were repealed, as well as all the acts of Henry VIII. upon religious matters, excepting those directed against the supremacy of the pope; and other acts relating to civil affairs were also abrogated. In the next session uniformity in public worship was established, in which the use of the book of common prayer, as prepared by the primate and his brethren, was enjoined. This composition is the foundation of that which, having undergone various alterations in subsequent reigns, continues in use at the present day. By one law the observance of fast days and of Lent was enjoined under penalties; and by another the English clergy were emancipated from compulsory celibacy.

The rest of this reign presents little but the history of the intrigues and cabals of courtiers. There was a war with Scotland, which began with injustice and was conducted with inhumanity. Insurrections also took place in Ireland, where the reformation made no progress. The details of these transactions will be given in the articles SCOTLAND and IRELAND. The protector was first opposed by his own brother Admiral Sir Thomas Seymour, who had married Catherine Parr, the late king's widow. She died soon after the marriage; and the widower is said to have then paid his addresses to the Princess Elizabeth. His brother the duke, who was at that time in the north, being informed of his ambitious projects, speedily returned, had him attainted of high treason, and at last condemned and executed. The Duke of Somerset himself, however, became unpopular, and a powerful confederacy was formed against him, at the head of which was Dudley earl of Warwick. This nobleman succeeded in overthrowing the power of the protector, and getting him committed to prison on the 13th of October 1549, whilst he himself was installed in the office of lord high admiral. In the month of February following Somerset was released upon payment of a fine and ransom; but towards the end of 1551 he was again sent to the Tower, tried for high treason and felony, and condemned. He was acquitted of the first charge, but not of the second, as he ought to have been. He suffered upon the scaffold on the 22d of January 1552. Warwick, now duke of Northumberland, had thus the reins of government entirely at his own disposal. Not satisfied with the office of protector, he aimed at altering the succession, and placing the crown upon the head of his son. He represented to Edward, who was now in a declining state of health, that his sisters Mary and Elizabeth, who were appointed by Henry's will to succeed to the crown, in failure of direct heirs, had both been declared illegitimate by parliament; that the queen of Scots, his aunt, stood excluded by the king's will; and being also an alien, lost all right of succeeding. The three princesses being thus excluded, the succession naturally devolved upon the Marchioness of Dorset, eldest daughter of the French queen, Henry's sister, who had married the Earl of Suffolk after her first husband's death. The next heir to the marchioness was Lady Jane Grey, the wife of Northumberland's fourth son, Lord Guildford Dudley. The king, who was accustomed to submit to the politic views of this minister, agreed to have the succession altered, and sketched with his own hand a draft of the new destination of the crown, which was submitted to a council. The judges, however, were far from acquiescing in the proposal contained in this instrument; and they hesitated to sign it, because it would subject those who had drawn and those who had advised it to the penalties of treason. Their hesitation excited the rage of Northumberland, who threatened them with his authority, and, pronouncing them traitors, declared that he would fight in his shirt with any man in so just a cause as that of Lady Jane's succession. A new paper was drawn up, by which the judges were screened from any consequences which might have resulted from their signing of it. By the new patent for changing the succession, the princesses Mary and Elizabeth were set aside, and the crown settled upon the heirs of the Duchess of Suffolk, who was contented to forego her own claim.

For some time the king had languished under a pulmonary complaint, and symptoms of an advanced stage of consumption began to make their appearance. After the settlement of the crown, his health visibly declined every day, and little hopes were entertained of his recovery. The deathbed devotions of Edward bear testimony to his love for his subjects, and his zeal for what he believed to be the purest form of Christianity. "O Lord, save thy chosen people of England, defend this realm from papistry, and maintain thy true religion." Such is a specimen of the supplications which this pious and short-lived prince breathed forth. On the 6th of July 1553, Edward, being then in the sixteenth year of his age and seventh of his reign, breathed his last. Whilst he filled the throne of England, no Roman Catholic had suffered death on account of his religion. By his gentleness and docility he was indisposed to shed blood, and, on the whole, his reign was more free from religious persecution than any administration of the same length, in any great country of Europe, since the rise of protestantism. In abilities he was equal, probably superior, to most boys of his years; but the flattering praises lavished upon him by his panegyrists are to be received with abatements. It was his dying wish that Lady Jane Grey, the companion of his infancy, should be his successor.

The death of Edward was carefully concealed for two days; but on the 8th of July the event was communicated to the ambassadors, and the civic functionaries of London were ordered to make preparations for the coronation of Lady Jane Grey. The intelligence was transmitted to Mary by her friends at court, and on the 9th she wrote a letter to the privy council, expostulating with them upon their conduct; and, solemnly affirming her right, she tendered a pardon to them if they would order her immediate proclamation. The council, however, adhered to the interests of Jane, and both parties prepared to decide the contest by an appeal to arms.

When Edward's death, and her own elevation to the throne, were announced to Lady Jane, she was thrown into a state of great agitation. The manner in which she was affected will be best understood from a passage in a letter of hers which she afterwards transmitted to Mary. "As soon as I had, with infinite pain to my mind, understood these things, how much I remained beside myself, stunned and agitated, I leave to those lords to testify who saw me fall to the ground, and who knew how grievously I wept." She urged the preferable claim of the princesses to inherit; but being pressed by the authority of the judges, she at length consented to accept of the royal dignity. She suffered herself to be conveyed to the Tower, and on the same day the heralds proclaimed the death of Edward and the succession of Jane. Mary was also proclaimed at Norwich, and it is somewhat singular that the populace took no interest in either of the proclamations. No shouts of applause or outward demonstrations of joy followed the announcement of the choice of a new sovereign. Northumberland was unpopular, a great part of the Protestants cooperated with the Catholic partisans of Mary, who were numerous and powerful; and the protector, by his supineness, allowed them to assemble in great force at Framlingham Castle, in Suffolk, where the princess had fixed her residence. Northumberland became alarmed, and although he had assembled a considerable army, his heart failed him when he saw the demonstrations which were made by the people in favour of Mary. He had taken the field in person, which was a fatal step; for his absence afforded an opportunity to the adherents of Mary who were in the council to make arrangements for exalting her to the royal dignity. It is sufficient to observe that they effected their purpose. Mary was proclaimed, and Jane, after a ten days reign, resigned the crown with a great deal more satisfaction than she had accepted of it. Northumberland had been compelled to proclaim Mary at Cambridge; but this did not prevent him from being led a prisoner to the Tower, which had lately been his palace.

Mary, accompanied by her sister Elizabeth, made her triumphal entry into London on the 3d of August 1553. Her attentions were first turned towards those who had suffered in her cause. She released several prisoners from the Tower, amongst whom were the aged Duke of Norfolk, and her kinsman Edward Courtenay, whom she soon afterwards created Earl of Devonshire. On the 18th of August the Duke of Northumberland, the Marquis of Northampton, and the Earl of Warwick, were tried for high treason; and on the following day Sir John Gates, Sir Henry Gates, Sir Andrew Dudley, and Sir Thomas Palmer, were tried for the same offence. Of the culprits who were condemned, three were selected for execution, Northumberland, Sir John Gates, and Sir Thomas Palmer, who suffered upon the scaffold on the 22d of August.

The mind of Mary now became solicitous about the affairs of religion. All the deprived Catholic bishops were restored. The acknowledged abilities of Gardiner soon raised him to the post of prime minister. He early received the custody of the seals, and not long afterwards he was appointed chancellor. The Protestant bishops, in the eyes of their Roman Catholic brethren, had incurred deprivation by marriage, or still more severe penalties by preaching heresy. On the 2d of September Cranmer was committed to the Tower, and on the 13th Latimer followed him into the same captivity. The latter, in point of moral heroism, was the antipodes of Cranmer, who was gentle and kind, timid and pliant. Latimer was brave, sincere, and inflexible. As he passed through Smithfield on his way to the Tower, he remarked, "Smithfield has long groaned for me." By an early proclamation Mary had declared that "she could not hide her religion, but that she mindeth not to compel any of her said subjects thereunto, until such time as a farther order by common consent shall be taken therein." The "farther order" did take place, although not in accordance with "common consent." On the 5th of October 1553, parliament assembled, and, in a session of nineteen days, passed only three acts; one for the abolition of all the treasons and felonies of Henry VIII.; another for the restoration in blood of Gertrude marchioness of Exeter; and a third for the like restitution of that lady's son, Edward Courtenay, now Earl of Devonshire. But on the 24th of the same month, several important acts were passed, by which the road was paved for the re-introduction of the Roman Catholic faith as the creed sanctioned by royalty. By these acts Henry's divorce was declared void, and his first marriage pronounced valid; so that the claim of Elizabeth, on whom the Protestants had fixed their eyes with anxious hope, was virtually set aside. But the progress of the revolution in religious matters was slow; and before the perfect re-union with the Church of Rome was consummated, several events of considerable importance took place. Mary having been crowned at Westminster with the usual solemnity on the last day of September 1553, it now became the interest of the Catholic party to obtain a suitable marriage for her. Of natives only two were proposed to her choice, both descended from the house of York; these were Cardinal Pole, and Edward Courtenay, the individual whom she had released from confinement. But the Emperor Charles having heard of Mary's intention to choose a husband, proposed his son Don Philip. This Spanish match was so broad and decisive a step towards Rome, that the House of Commons took the alarm, and presented an address to the queen, in order to dissuade her from her purpose. She returned a haughty answer; and on the 30th of October, having conducted the imperial minister into her private oratory, she there solemnly called God to witness that she plighted her troth to Philip prince of Castille. To obviate all clamour, the articles of marriage were drawn up as favourably as possible for the interests of England. It was agreed that though Philip should have the title of king, the administration should be entirely in the queen; that no foreigner should be capable of holding any office in the kingdom, nor should any innovation be made in the laws, the customs, and the privileges of the people; and that Philip should not carry the queen abroad without her consent, or any of her children without the consent of the nobility. Sixty thousand pounds a year were to be settled upon her as a jointure, and the male issue of this marriage were to inherit Burgundy and the Low Countries as well as the crown of England; and in the event of the death of Don Carlos, Philip's son by his former marriage, without any heir, the queen's issue were also to inherit the rest of the Spanish dominions.

All these concessions, however, were not sufficient to quiet the apprehensions of the people. They were considered merely as words of course, which might be retracted at pleasure; and the nation murmured loudly against a transaction so dangerous to its ancient liberty and independence. The Duke of Suffolk, a zealous Protestant, attempted to excite his tenants in Warwickshire to revolt; but with little success. His followers were routed by Lord Huntingdon, and he himself was betrayed into the hands of his enemies. An insurrection was also raised by Sir Thomas Wyatt, a Roman Catholic, at the head of four thousand men, who set out from Kent to London, publishing a declaration against the Spanish match and the queen's evil counsellors. Having advanced as far as Southwark, he required that the queen should put the Tower of London into his hands; that she should deliver four counsellors as hostages; and that, in order to ensure the liberty of the nation, she should marry an Englishman. But his force was still by far too inconsiderable to support such magnificent pretensions, although it was afterwards augmented to fifteen thousand men; and he unluckily wasted so much time without attempting any thing of importance, that the popular ferment entirely subsided, his followers gradually abandoned him, and he was at last obliged to surrender himself near Temple-Bar to Sir Maurice Berkeley, who committed him to the Tower, where, in a short time, he was joined by the chief of the surviving conspirators. The nobility and gentry immediately repaired to St James's to congratulate the queen on the suppression of the rebellion. But two were excepted; Courtenay duke of Devonshire, and the young Earl of Worcester, who, on the first approach of the enemy, had turned their horses' heads and fled. On the 3d of November 1553, Lord Guildford Dudley and Lady Jane Grey had been convicted of high treason. Lady Jane and her husband were both only in their seventeenth year, and no time was fixed upon for their execution; but the revolt of Suffolk, Lady Jane's father, proved an incentive sufficiently strong to prevail over the slender pity of bigots and politicians, and the sacrifice was consummated.

On the 8th of February Mary signed a warrant for their execution, and on the 12th of the same month it was put in force. Lord Guildford Dudley had requested an interview with his beloved wife, who, however, declined the meeting, justly fearing that it might unfit them for the dreadful scene through which they were about to pass. She saw him issue through the gate of the Tower to the scaffold; and soon afterwards, in chancing to look from the same window, she saw the bloody carcass, half covered in the vehicle which bore it back from the place where vengeance and injustice, disguised under the name of law, had done their worst. Lord Dudley was beheaded on Tower-Hill; but his wife, on account of her royal descent, was spared the ignominy of a public execution. Lady Jane Grey is celebrated as exhibiting a matchless union of beauty with genius, and learning with virtue and piety. She astonished the learned of Europe by her talents and accomplishments, and will be recognised by all posterity as one of the purest and most amiable of historical characters. Were Mary chargeable with no other atrocity than that of putting Lady Jane to death for the crime of a father (for it was on his account that the daughter suffered), it were quite sufficient to cover her memory with irremoveable degradation. "It was a death," says Sir James Mackintosh, "sufficient to honour and dishonour an age." Suffolk, her father, perished in the same manner a few days afterwards. Sir Nicholas Throgmorton was tried, but the defence which he made was found so good in law, that the jury acquitted him. Above sixty others of the conspirators were condemned to the block, amongst whom were Lord Thomas Grey the brother of Suffolk, and Wyatt the principal mover of the rebellion.

This revolt had very nearly proved fatal to the Princess Elizabeth, who for some time had experienced harsh treatment at the hands of her sister. Mary, upon whom the mantle of Henry VIII. had descended, felt antipathy to her on account of the quarrel between their mothers. This circumstance, in the mind of one whose tender mercies were cruel, was sufficient to change the milk of sisterly affection into mortal venom; and a favourable opportunity was only necessary to make her feel its deadly effects. Nearly a month was spent in labouring to extract information against Elizabeth from Wyatt whilst he lay in prison. But the unfortunate gentleman honourably acquitted her, although he might, in all probability, have saved his own life by implicating her in the late rebellion. At Ashridge, whither she had retired to escape the constrained participation in a worship which she disapproved, overtures had been made to her by the chiefs of the revolters; but her acceptance or consent was neither shown nor seriously alleged. Immediately after Wyatt's discomfiture, she was conducted to London in a very infirm state of health. It was doubted whether she would reach her destination alive; but youth and strength triumphed over the malady with which she was affected. Courtenay earl of Devonshire was also arrested, and committed to the Tower. Two councils were held on the fate of Elizabeth, and the judges were divided in their opinions as to her guilt. Gardiner, although he professed to think Elizabeth deserving of death, yet considered her confinement at Ashridge, and Courtenay's residence at St James's, as irreconcilable with a just conviction of treason. The head and front of her offending seems to have been misprision, or concealment of projects of revolt, which was now not a capital crime. It was fortunate for Elizabeth that one of the first measures of her sister, when she ascended the throne, was to sweep away the odious heap of treasons raised up by her father, and the punishment of misprision with death was one of them. But Elizabeth, although absolved from a capital charge, was nevertheless committed to the Tower; and shortly afterwards she was put under the charge of Sir Henry Bedingfield, keeper of Woodstock. During her stay in the Tower, the princess had no other expectation than that of mounting the scaffold which had been trodden long before by her unhappy mother, at her father's stern behest, and on which the blood of Lady Jane Grey, the purest of the pure, was scarcely dry. When Bedingfield came with his soldiers to conduct her to Woodstock, she asked, with her usual quickness and poignancy, "Is the scaffold of Lady Janet taken away?" A few days later, Courtenay was transferred from the Tower to Fotheringay Castle.

The rebellion had suspended for some weeks the proceedings relative to the queen's marriage. But in the beginning of March the English ambassador returned from the Continent with the ratification of the treaty; and Philip landed at Southampton on the 19th of July 1554, attended by a magnificent train of Spanish grandees and Burgundian lords. The marriage between him and Mary was solemnized by Gardiner in his cathedral at Winchester, before crowds of noblemen from all parts of Christendom, and with a pomp and splendour seldom surpassed. Philip was then in the twenty-ninth year of his age, and Mary in her thirty-eighth year. The countenance and form of the prince were far from being disagreeable; but the stately reserve of his Spanish manners was not calculated to lessen the repugnance of the English people to the union.

Soon after her marriage, Mary resolved to restore the religious polity of the kingdom to that state in which it had existed at the time of her birth. Accordingly, on the 12th of November a parliament was holden for this purpose, and a bill passed both houses "for the restitution in blood of the Lord Cardinal Pole." But a difficulty arose regarding the abbey lands; for it was feared that those who possessed them in spite of the indelible claims of the church might be called before the tribunal of the pious cardinal. However, on the 20th of November, Pole arrived at Dover, armed apparently with ample powers to do every thing necessary for the reconciliation of England with the church of Rome; and amongst these was full authority to do with the abbey lands as he thought fit. Nine days after his arrival, he made an oration to the two houses, exhorting them to return to the bosom of the universal church, at the same time absolving the kingdom from the papal interdict. The request was formally acceded to, and Pole was enabled to announce to the pontiff the success of his mission. In order to quiet the possessors of church property, the legate issued his dispensation, declaring that they should not be molested; and a statute passed confirming his sentence. By another, the acts which had abolished the papal supremacy were repealed. This new restoration of power to the papacy formed a sad and dark augury for the devoted Protestants. It was the first indication that the time approached when the fires of persecution were to blaze forth in every county of England, and when heaven was to be insulted by the profanation of its sacred name as sanctioning the foulest deeds of blood.

An act was passed by the parliament of 1554 for the revival of the statutes of former sovereigns against heretics, and especially against Lollards; which revival was to take effect from the 20th of January 1555. During the last reign, no Roman Catholic had suffered capital punishment on account of his faith, nor does there appear to have been any kind of jurisdiction or mode of procedure for the trial of heresy, although the law remained in full force against anabaptists and anti-trinitarians, whose doctrines were looked upon both by Catholics and Protestants as sapping the very foundations of Christianity. It has been alleged by the opponents of Protestantism, that in *The Reformation of Laws*, composed in the latter part of Edward's reign, there are indications of a preparation for lighting the faggot against the adherents of the ancient religion; and as the point is of some importance, we shall avail ourselves of the following observations by Sir James Mackintosh, which seem to put the matter in its true light. Referring to the allegation that severity against the adherents to Catholicism was about to be put in execution, he says,

"This statement is chiefly grounded on a text of that projected code, which directs that contumacious and incorrigible heretics, after all other means have been exhausted, shall be at length delivered to the civil magistrate to be punished. It is assumed that the punishment must be death. Yet in the very first article of the code, which relates to atheists and unbelievers in Christianity, death is denounced against them in express words.

"The admission of it into another article by mere implication is therefore unreasonable. It is too terrible an enactment to be admitted without express words. If punishment is held to be synonymous with capital punishment, by force of this clause death must be applied to all heresies. If it was intended to confer on the civil magistrate a large discretion in the infliction of inferior punishments for the enumerated heresies, the article is perfectly agreeable to the practice of the framers and the opinions of the times. It is incredible that capital punishment could be denounced against the whole of a long series of heresies, of which the catalogue nearly occupies twenty quarto pages, besides what is called a monstrous heap of other errors, less necessary to be specified, as being less prevalent in that age. Even admitting this unreasonable construction of the plan for a reformed code, it affects only the reputation of the projectors. It never was adopted by public authority. It was not laid before parliament. There is no reason to doubt that the Protestant parliament would have altered the very articles in question, if, when they were communicated to that assembly, they could be supposed to establish or countenance a practice perfectly at variance with that of the king and parliament of England in the reign of Edward VI. To hold that a few words in a Latin manuscript, of projected but not adopted laws, not printed till many years afterwards, could have been the incentive of those who kindled the fires of Smithfield under Mary, is one of the most untenable of all positions. Truth and justice require it to be positively pronounced, that Gardiner and Bonner cannot plead the example of Cranmer and Latimer for the bloody persecution which involved in its course the destruction of the Protestant prelates. The anti-trinitarian and the anabaptist, if they had regained power, might indeed have urged such a mitigation, but the Roman Catholic had not even the odious excuse of retaliation."

The year 1555 opened with gloomy forebodings for the reformed clergy; and ere a month had expired, the lowering tempest burst upon them with unexampled fury.

On the 28th of January a commission, with Gardiner at its head as lord chancellor, assembled in the church of St Mary Overies, in Southwark, for the trial of Protestants. From the station which this individual held, and from his commanding talents, there appears to be little doubt that he was instrumental in pushing forward this bloody work, although some writers have attempted to remove this reproach from his character. Whether he was the main author or not, is a matter of comparatively little importance. As lord chancellor, and as head of the commission, he sanctioned the whole proceedings. He must therefore be held responsible for the deeds of those who acted under his authority, and suffer the lash of posterity, in the same way as Cromwell, on whom Catholic writers have poured out the vials of their wrath, from his having acted as captain of the banditti who plundered the holy places in the reign of the eighth Henry.

The first martyrs in this persecution were Hooper bishop of Gloucester, and Rogers, a clergyman of Essex, both eminent divines of the reformed cause. They died with feelings of triumphant piety in the midst of suffocating flames; and other victims were rapidly hurried to the stake. The principal were, Archbishop Cranmer, Ridley bishop of London, and Latimer bishop of Worcester. (See CRANMER.) These persecutions soon became odious to the whole nation, and the perpetrators of them were all willing to shift the blame from themselves upon others. Many of the Catholic prelates, to their honour, exercised occasionally an effectual and perhaps hazardous humanity in their favour. Gardiner himself withdrew from this unavailing slaughter, and his place was supplied by Bonner bishop of London, a less scrupulous dealer in blood. Even Philip himself was moved to pity, and discountenanced these diabolical proceedings. To describe the sufferings of those persons of eminence and distinction who perished, would fatigue the patience and harrow the feelings of the reader. For four years the persecution was carried on with unsatiated cruelty; and, keeping out of view those who perished in dungeons under every form of misery, and also those who expatriated themselves, nearly three hundred individuals are calculated to have expired at the stake. We are positively informed by Lord Burghley, that in this number of victims are comprised no less than one hundred women and children. The perpetrators of these "more than heathen cruelties" deserve no quarter from posterity; such deeds as those laid to their charge stamp infamy deep on their names, and hold them up to execration now and for ever.

The other events of this reign unconnected with religion are, with the exception of the loss of Calais, unimportant. The reduction of this town had cost Edward III. a siege of eleven months, and the English standard had waved over its battlements for above two centuries. It surrendered to the arms of France after a siege of only eight days, and its loss so affected the queen, that when lying on her deathbed she said, "If you open me you will find Calais written on my heart." Philip, her husband, appears to have treated her with formal but cold respect.

He had succeeded to the greatest monarchy then in the world, and had been some time absent from England in superintending its affairs. He returned again, but his departure a second time left Mary to brood over her fruitless barbarity alone. She had more than once entertained the nation with rumours of her pregnancy, and was herself cheated with the illusive hopes of offspring. But this Shiloh of the ancient faith, like that of a celebrated dreamer of after times, was the manifestation of a deadly disorder. She died of dropsy on the 17th of November 1558, to the unspeakable relief of the greater portion of her subjects.

It is customary to load the name of Queen Mary with every kind of opprobrium. But in estimating human character, care should always be taken to distinguish between acts committed under the influence of religious principles, and agreeably to conscience, however erroneous such convictions may be, and those perpetrated from the sheer brutality of passion, or from an instinct of cruelty and bloodshed. That the atrocities of Mary belong to the former class of crimes, we have little hesitation in saying, even with the case of Lady Jane Grey before us. Her ministers, also, must share with her no inconsiderable portion of the odium which is always associated with her reign, for to their errors or prejudices much of the misery which she caused must be ascribed.

Although in the private life of Mary there is much to praise, yet her nature was sour and unamiable, and almost destitute of that tenderness which peculiarly distinguishes the female character. Whether or not she was a tyrant like her father, she was at all events pre-eminently fitted for becoming the tool of tyrants. She was not remorseless, for she is reported to have suffered much on account of her conduct towards the Protestants, but unfortunately her conscience never took effect in time.

After the death of Mary, the Princess Elizabeth succeeded to the throne without opposition. She was at Hatfield when the news of her sister's death were brought to her, and hastening to London immediately, she was received there with great joy. For the preservation of her life this princess was indebted to Philip, the husband of Mary. The Spaniard was aware that her death would remove the only obstacle which stood between Mary of Scotland and the throne of England. That sovereign had been married to the heir-apparent of France, his great political enemy; and the balance of power which might thus be thrown into the hands of the latter would have endangered the stability of Philip's throne; a circumstance which induced him to this unusual act of liberal humanity. The first measure of Elizabeth was to assemble around her throne a body of counsellors who had recommended themselves to public notice by the power of their talents or the steadiness of their principles. Her state council was composed of both Catholics and Protestants, although her more confidential advisers were confined to a select portion of the latter, and amongst these was Sir William Cecil, whom she appointed her first secretary. Precautionary measures were taken to meet any invasion on the part of France in order to raise Mary Queen of Scots to the throne; for the government of that country had made demonstrations to this effect, by instigating Rome to hostilities against Elizabeth. Mary had left a vacant treasury, and one of the first cares of the new administration was to obtain pecuniary supplies; and, from the high character and popularity of the queen, these were immediately granted by the people. Her coronation was then celebrated with all possible splendour and festivity.

To establish the Protestant religion was Elizabeth's most ardent desire. With this view the statutes passed in the late reign for the support of the ancient faith were repealed; and the acts of Henry VIII. in derogation of the papal authority, and of his successor in favour of the reformed church, were for the most part revived. There were some deviations in the new book of common prayer from the liturgy of Edward VI., but of these only two are important. The first consists in the omission of a prayer to be freed from the "tyranny of the bishop of Rome and all his detestable enormities;" which certainly displayed a conciliatory spirit towards the Catholic church. The second was an alteration of the language which spoke of the sacrament as being only a remembrance of the death of Christ, and the substitution of words which indicate the real but not corporeal presence. Towards the middle of 1559 the Protestant liturgy was introduced, and the oath of supremacy administered. Strong opposition to it was evinced on the part of the clergy, especially amongst those of a dignified station; and out of sixteen bishops only one took the oath tendered to them. But the lower orders were less scrupulous; and it is probable that in many instances necessity induced them to make a compromise with their consciences. Those of the clergy who refused compliance with the new code of religious doctrines were deposed, and their places supplied by professors of the reformed religion. According to the standard of punishments which followed contumacy in these ages, the treatment of the bishops was mild. Bonner was imprisoned; but he was a man so empurpled with blood as to be odious to all parties. This was the highest degree of suffering to which any of the nonconformists were subjected.

During the time that the queen and her counsellors were thus settling the religious affairs of the nation, negotiations were carried on between England and France for a peace, which was at last concluded on the following terms, viz. that the French king should restore Calais at the expiration of eight years; that in case of failure, he should pay five hundred thousand crowns, and Elizabeth's title to Calais should still remain; that for the payment of this sum he should find the security of eight foreign merchants, not natives of France; and that until such security was provided he should deliver five hostages. If during this interval Elizabeth should break the peace with France or Scotland, she was to forfeit all title to Calais; but if the French king was to make war on Elizabeth, he was to be obliged to restore the fortress immediately.

The reign of Elizabeth for the first eleven years, that is, from the twenty-fifth to the six and thirtieth year of her life, was distinguished for the internal quiet and happiness of the country. During this interval she displayed the very best qualities of a sovereign; firmness, prudence, vigilance, activity, and foresight. These qualities were tempered with habitual amenity, and a rational piety. By her subjects she was admired, applauded, and imitated; and during this halcyon period her throne received an accession of strength which enabled it to stand unshaken amid the tumultuous storms with which it was afterwards assailed. She was repeatedly advised to engage in a matrimonial alliance, but uniformly declined to do so, declaring her resolution of remaining single for life. Amongst her suitors were various foreign princes, Catholic as well as Protestant; and some of her own subjects even presumed to intrude their offers upon her "maiden meditation," but without success. During the religious war which raged in France, Elizabeth, ever ardent in the cause of the reformation, assisted the Huguenots with arms and money.

In the mean time the pretensions of Mary, queen of Scotland, to the crown of England, involved Elizabeth in transactions which have left a stain upon her name. Mary, who was espoused to the dauphin of France, had quartered the arms of England with those of France and Scotland upon her escutcheon; and to this she was advised by the Catholics, who looked upon Elizabeth as a usurper, having been illegitimised in her youth by the cruel mandate of her father at the time when he consigned her mother to the block. The result of this appropriation of the armorial bearings of the English sovereign was a quarrel between the two princes, which only terminated with the execution of the unfortunate queen of Scotland. See the articles MARY and SCOTLAND.

In 1569 Elizabeth was excommunicated by Pope Pius V. These anathemas, by absolving subjects from the oath and the duty of allegiance, and suspending the offices of religion, and even those of humanity, were sometimes most disastrous to a country, upon which they descended like a deadly epidemic. But the majority of the queen's subjects were of the same religion with herself, and had thrown off the papal yoke; so that it was in the present instance productive of no other effect than the publication of a severe act against all who held any communication with the bishop of Rome. Severe measures were also taken with the puritans and other dissenters. At this time the English nation was divided into three theological and political parties; the *Churchmen*, who considered the ecclesiastical revolution as already perfect; the *Puritans*, who sought further reformation by agitating the minds of the people; and the *Catholics*, who, supported by the great continental powers, did not yet despair of seating their religion upon the throne. But men of all these persuasions united in their abhorrence of anabaptists; and, in order to extirpate them, the fires of Smithfield were, after an interval of seventeen years, re-kindled. Fox the celebrated martyrologist dared to interfere in behalf of this hated sect; but his courageous humanity obtained for them only a temporary respite. Two men were burned, and numbers were imprisoned or otherwise corporally punished. These events took place about the middle of the year 1575, and this was the first blood spilt by Elizabeth on account of religion; it, however, forms a dark stain upon her government, which may be pronounced mild when compared with others of the same period. The blood of Henry VIII. was not yet sufficiently purified in this its first descent from the fountain-head.

Amongst the other domestic events connected with the history of England, was that of the rebellion of Percy earl of Northumberland, and Neville earl of Westmoreland. This revolt partook both of a civil and of a religious character, for the noblemen at its head were adherents of the ancient faith, and were encouraged to embark in their lawless enterprise by the Catholic states. But on the approach of the royal troops under Sussex, the insurgents broke up and fled. Northumberland was made prisoner in Scotland, and executed at York; and Westmoreland died in Flanders, in the humble capacity of commandant of a Spanish regiment. Other treasonable transactions originated with the Duke of Norfolk, whose vaulting ambition aspired to the hand of Mary queen of Scots. Indeed he and the two insurgents just named, together with several other nobles, united in a conspiracy against Elizabeth. The timely arrest of Norfolk, however, disconcerted the confederacy, of which the northern rising was merely a premature explosion. Mary of Scotland is positively asserted to have been a participator in the plot. Norfolk was brought to trial; and there seems little doubt that he had incurred the penalties of treason, by having had intercourse with Catholic princes who had undertaken to land in England with a hostile army, and by his clandestine renewal of negotiations for the delivery and espousal of Mary, at that time a prisoner in the hands of Elizabeth. He was condemned to death, and executed, after a great deal of hesitation on the part of the queen.

England now began to distinguish herself in her natural career of maritime enterprise. Amongst the most distinguished of the nautical adventurers of this age was Sir Francis Drake, whose exploits will be found related under the article DRAKE. A vague rumour had for some time pervaded Europe, of vast naval preparations by the king of Spain, for the invasion and conquest of England. In 1587 Sir Francis Drake having been dispatched with a fleet to attack the Spanish ships which lay in the bay of Cadiz, was completely successful in his enterprise, burning and destroying above one hundred vessels laden with ammunition and naval stores. The fruits of his expedition were of vast importance. Philip's preparations were disturbed, and his project of invasion put off for twelve months, during which period Elizabeth had time to make head against the storm which was gathering in that quarter. These were the obvious results of Drake's bravery; but who can estimate the moral effect which it had produced? It gave a heroic impulse to the nation, and inspired it with confidence in its own strength and resources. It taught English seamen to look without terror upon the towering bulk of the Spanish vessels; whilst the Spaniards themselves must have in a proportional degree lost the confidence of having an advantage over the enemy by means of their floating castles.

The king of Spain having once more completed his complement of vessels, manned them with the ablest seamen and soldiers, under the command of the most renowned leaders. This Armada was truly imposing and magnificent; it was baptized The Invincible, but not with English blood. Never before had the ocean borne a more splendid fleet than that which sailed from the Tagus on the 25th of May 1588. The ships and their equipments had been fitted out in every port of its king's dominions. In Flanders, the forest of Waes had been felled; the dockyards of Antwerp, Dunkirk, Newport, and Gravelines swarmed with artificers; and the rivers and canals were covered with boats adapted for the transport of soldiers destined to serve in the expedition. On the 20th of May the following enumeration of the vessels was made: "The general sum was 130 ships, of 57,868 tons; 19,295 soldiers and 8450 mariners, with 2088 slaves, and 2630 great pieces of cannon of all sorts; also twenty caravals for the service of the others, with ten salvers of six oars a piece." Towards the end of June another armament of eighty sail left Lisbon to join them.[1] To meet this overwhelming armament the royal navy of England mustered 181 ships, containing between seventeen and eighteen thousand seamen. There were only eight ships above five hundred tons burden, and the largest was only eleven hundred. The aggregate burden of the whole English fleet amounted to 31,985 tons, being little more than one half of that of the Spaniards. The preparations made on land displayed equal spirit and enthusiasm. A loyal patriotism and active magnanimity pervaded the whole kingdom. The city of London set a noble example. The lord-mayor, in the name of the metropolis, put at the disposal of his sovereign ten thousand soldiers and thirty vessels. The whole nation emulated this wise liberality; and every city, town, and hamlet poured forth its ardent patriots to take their stand upon the coast and repel the insulting invader. About fifty thousand men under the command of Earl Hunsdon, a brave and able general, guarded the queen's person. The Thames at Tilbury was watched by Leicester with a considerable force. Sir Walter Raleigh was stationed at Portland Castle, in Dorsetshire, and the Earl of Sussex at Portsmouth. In the other parts of the country the wisest measures of defensive warfare were adopted. At sea one division of the fleet under Lord Henry Seymour guarded the narrow seas; whilst the main body under Lord Charles Howard, the high admiral, was stationed in the Western Ocean. The gallant Sir Francis Drake and the able navigators Hawkins and Frobisher were in this division.

---

[1] Strype, p. 538-9, from the Spanish book, which rather styled the whole "Felicissima Armada."

Under the Duke of Medina Sidonia, the Spanish Armada set sail for the invasion of England. It was for some time retarded by a tempest, which also harassed the English fleet; and news were brought to the queen of England that Medina's Armada had been so injured and scattered that the expedition was for the present abandoned. The English ships withdrew to various ports, where they might have been surprised and burned, had not intelligence accidentally arrived that the Spanish fleet was bearing down full sail upon the coast. On the 20th of July the English admirals came in sight of the enemy, and next day the first engagement took place. The plan of Lord Howard was to evade a direct attack; for his vessels being so much inferior in bulk and weight of metal to the enemy's ships, were incapable of grappling in close action with them; but being superior in mobility and expedition, he resolved to annoy their rear, and to cut off the sluggish sailers. In the first attack neither fleet suffered much. Early in the morning of the 23d the second conflict began, and both fleets fought with valour; but the advantage was at last on the side of the English, over whose smaller vessels the iron shower from the higher sides of the Spanish ships flew harmless, whilst their own took full effect. On the 24th a pause took place in the battle, which was, however, renewed next day; but the mighty armament forced its way unbroken to the vicinity of Calais. They were now prepared to act in concert with the Duke of Parma, who had completed his preparations. He possessed in the harbours of Newport and Dunkirk transports which carried about twenty-eight thousand men, and which waited the general's command to make the grand attempt.

The concentration of the Spanish Armada off Calais suggested to the English admiral the idea of employing fireships to destroy it. Eight vessels were thereupon hastily prepared for this purpose, and during the night of the 29th, which was cloudy and boisterous, they were sent down blazing with combustible materials into the heart of the Spanish fleet. A cry of horror burst from the Spaniards, and, seized with an irresistible panic, they cut their cables with the intention of standing out to sea. But in their terror and confusion they inflicted severe injury upon one another; and, to augment their distress, a fierce gale sprung up, which scattered the Armada along the coast from Ostend to Calais. Some struck on the shallows at Flanders, whilst others beat out to sea; the remainder, amounting to about forty sail, were assailed by Drake and the rest of the English fleet. This was the most severe engagement which had yet taken place, and was maintained with great bravery for a whole day. The Spaniards lost several of their best ships; and after vainly endeavouring to regain their position in the narrow strait, where Parma could alone join them, they resolved to return to Spain by making a circuit round Great Britain. The want of ammunition compelled the English to refrain from pursuing the invaders at a time when they might have annihilated them. But this was reserved for an enemy even more formidable than that before which they fled. A storm overtook them on their unfortunate voyage, and the coasts of Scotland and Ireland were strewed with the wrecks of the Invincible Armada, so that only a feeble remnant of that splendid fleet reached the shore from whence it had sailed, in all the pomp and circumstance of war, as if to an assured triumph.

The events of Elizabeth's reign which followed the discomfiture of the Spanish attempt to invade England may be briefly related. The Earl of Leicester, who had for a long time maintained an enviable place in the queen's favour, was invested with fresh honours. A new and unprecedented office was created for him, that of lord lieutenant of England and Ireland, which exalted him to an authority only a little lower than that of sovereignty. But the ink was scarcely dry upon the warrant which wanted but the royal signature to complete the triumph of the favourite, when he was cut off by a violent disease, which, whether it arose from natural causes, or from poison being administered, at all events speedily terminated his career. Of this nobleman little need be said. He is one of a numerous class of historical characters who possess a degree of notoriety, not on account of any brilliant endowments which they themselves possessed, but from their proximity to or connection with distinguished personages. He possessed no intellectual or moral qualities which, deprived of adventitious aid, would have thrown him into the foreground of his country's history; whilst, if we listen to the opinion of his contemporaries, he must be looked upon as dissolute and unprincipled, notwithstanding his affectation of piety. He is a satellite only conspicuous from the light which is reflected upon him by his sovereign.

The English navy, emboldened by its late triumph, now made several very successful descents upon the Spanish coast, not so much for the purpose of obtaining permanent conquest, as of harassing the enemy. These expeditions were conducted by the most able commanders, amongst whom were some of the brightest names in the history of maritime discovery and enterprise, such as those of Raleigh, Drake, Cavendish, Hawkins, and Howard. It was then that the English navy assumed the empire of the sea, which it has ever since maintained with triumphant heroism.

On the death of Leicester, the young Earl of Essex succeeded him as prime favourite of the queen. But the desire of glory or the hope of plunder induced this volatile young nobleman to join the armament preparing to sail for Spain. The expedition was unfortunate, and when Essex returned to England, he found two rival candidates for royal favour, Sir Walter Raleigh and Sir Charles Blount. By the superior influence of these noblemen, the former was driven to cultivate a portion of land which had been granted to him in Ireland; and with the latter Essex fought a duel, in which he was wounded. But by the queen's command they were reconciled to each other, and in process of time they became sincere and attached friends.

In the year 1596, a new expedition was fitted out for Spain, which was completely successful. The Spanish fleet was defeated, and lost thirteen men-of-war. Cadiz was taken, and its defences, which rendered the town the strongest fortress in the country, were razed to the ground. This was the severest blow which the king of Spain received from his daring enemy subsequent to the repulse of the Armada. Matters might have been still worse with him had not dissension sprung up amongst the English commanders, the majority of whom, against the suggestion of Essex, who was one of the leaders, declared for an immediate return to England. The town, with the exception of the churches, was reduced to ashes; and the troops, taking with them the most valuable portion of the plunder, re-embarked, and the fleet returned to Plymouth in less than ten weeks after it had set sail. Essex, on his arrival in England, was compelled to appear before the queen in council, and answer to several charges connected with the late enterprise. These charges merely related to pecuniary matters, and the favourite was acquitted; but this was the commencement of numerous subsequent quarrels which he had with his sovereign, none of which are important to history except the last. Having been appointed lord deputy of Ireland, he suddenly left his command in that country and returned to England. He was committed a prisoner, and called upon to account for his extraordinary conduct. The queen, however, was unwilling to carry matters too far against her favourite. He was allowed to go about as a prisoner on parole; but this high-spirited and aspiring nobleman could not remain content with the humiliating circumstances to which he was now reduced. He attempted to excite the city of London to revolt against the queen's authority; but the rebel was taken prisoner, tried for high treason, condemned, and executed. This proved a severe blow to Elizabeth, who was now tottering upon the brink of the grave. She had been all her life subject to fits of indisposition, which were occasionally violent; but it was not till the beginning of March 1603 that her mortal illness came on. Her mind became depressed with gloomy recollections, especially those connected with the shedding of Essex's blood; and her nervous melancholy and general decline increased, accompanied by symptoms which indicated a disease of the heart, and by a laboured and convulsive respiration. She was questioned by her confidential advisers as to her successor, and signified her desire that the king of Scotland should succeed to the throne. Her speech soon afterwards failed entirely, and all hope of her recovery vanished. She tranquilly breathed her last, about three hours after midnight, on the 24th of March 1603, in the sixty-seventh year of her age and forty-fifth of her reign.

In the opinion of her contemporaries, whose judgment has been ratified by posterity, Elizabeth ranks amongst the greatest and the most fortunate of English sovereigns. The domestic tranquillity which signalized her rule during nearly half a century; her triumphant repulse of the Spanish monarch, and the severe retaliation which she inflicted upon that lord of empires; the spirit displayed by her navy in its numerous warlike expeditions by sea, and also by her army on land, are indications of uncommon vigour on the part of the sovereign, and of sagacity on that of her counsellors. She found England comparatively inferior to other nations of Europe, but she left it amongst the proudest and the most powerful. It was during her reign and that of her successor, that the human intellect sprung up at once to full maturity, and produced those works which are the peculiar glory of English literature. Hers was the Augustan age of poetry, the age of Spenser, Shakspeare, and others; and during her reign Bacon began to put forth those gigantic energies of mind which were destined to change the whole aspect of science, and even the condition of man as a civilized being. The human failings ascribed to Elizabeth are, excessive vanity, love of popularity which is part of it, parsimony, and a leaning towards despotism. But those whose interest it has been to vaunt the glory of her sister's reign, and the purity of her life, have not failed to charge Elizabeth with great personal depravity; yet if we discredit every defamatory story which can be clearly traced to her enemies, the imputations will not have much weight, or attach any grave stigma to her name.[1] She is not, however, free from the stain of blood, the shedding of which cannot be justified, however it may be palliated by taking into account the circumstances of the times, and the critical situation in which she stood; but in this respect her conduct is almost purity itself compared either with that of her sister or of her father. For an account of the private life and literary character of this great queen, see the article ELIZABETH.

She was succeeded by James the Sixth of Scotland and First of England. From that period, the history of the countries is given under the article BRITAIN.

PART II.

STATISTICS.

I.—*Situation, Extent, Face of the Country, Soil, and Climate.*

tuation d ex- nt.

England, the southern, and by far the most fertile division of Britain, corresponds in latitude with Holland and the north of Germany, extending from 50° to 55° 45′ N. Its figure is nearly triangular, and its extent of coast is very great, both from being much indented, and from the sea bounding it on all sides except along a width of seventy miles on the Scottish border. The adjacent seas are the German Ocean on the east, St George's Channel on the west, and the English Channel on the south. No country can be more fortunately situated; its climate is temperate; its extent is sufficient for its political security; whilst its insular position not only presents the greatest capabilities of aggrandisement in a commercial sense, but has, by rendering a great military force unnecessary, in all probability been the chief cause of preventing the executive branch from usurping absolute power, as in the countries of the Continent.

Its superficial extent had long been a question of considerable doubt, and the different estimates varied no less than ten millions of acres. Mr Pitt, on the authority of Arthur Young, assumed, in 1798, the superficial extent of England and Wales to be nearly 47,000,000 of acres; a later calculation by Dr Beeke, approaching more to accuracy than any preceding one, fixed it at 38,500,000 acres;[2] but, according to Arrowsmith's map, which, as it is principally founded on the trigonometrical survey, cannot involve any material error, the area of England and Wales amounts to 57,960 square miles of 69·15 to the degree, or to 37,094,400 imperial acres. This is the measure that is now adopted in all the parliamentary reports.

Face of the country.

England is, in general, a level country. In the north, Westmoreland, and a considerable part of Cumberland, Lancashire, and Yorkshire, are mountainous; but most of the other counties present a succession rather of picturesque eminences than of great elevations, forming a striking contrast to the barren ridges of the northern part of the island, and still more to the abrupt and awful scenery of Switzerland or the south of Germany. The highest mountains of England are in the north-west, where there are several exceeding 3000 feet in height; of these, the most noted, if not the highest, is Skiddaw. Between Lancashire and Yorkshire there is a range of nearly equal altitude; in Shropshire there are various hills; also in Somerset, Devon, and Cornwall, none of which, however, reaches the height of 2000 feet. There is a long hilly range which traverses the southern counties, in a line nearly due east and west from Dorsetshire to Kent; and another that stretches in a north-east direction from Wiltshire to the East Riding of Yorkshire; but both are of inconsiderable elevation. The traveller who proceeds northward from London to York meets very few hills, and hardly one mountain, in a distance of 200 miles. To the east of this road, the country, particularly Cambridgeshire, Lincolnshire, and part of the East Riding of Yorkshire, is almost entirely level, and bears a great resemblance to Holland; consisting of fens apparently gained in a very remote age from the sea. In Wales the face of the country is altogether different, being mountainous throughout, and some of the hills, in particular Snowdon and Cader Idris, attaining a height nearly 3600 feet above the level of the sea.

---

[2] Observations on the Produce of the Income Tax, &c. 1800.

Sea-coast.

The sea-coast of England presents a very different aspect in different situations; in some quarters, as in Cornwall, Kent, part of Norfolk, and Wales, it is steep and elevated; in other parts it is low, sandy, or marshy; exhibiting, on the whole, a variety which hardly admits of being brought under a uniform description, and which, though partaking much more of a level than rugged character, still differs greatly from the opposite shore of Flanders, Holland, and Friesland, which is one continued flat for more than 300 miles.

Rivers.

Of the rivers of England, the largest are the Thames, the Severn, and the Trent. The Thames has no pretensions to romantic effect in any part of its course, nor is its body of fresh water large; but it is navigable for more than 120 miles, and, in the approach to London from the Nore, presents to the admiring spectator a prospect which, whether we consider the quantity of shipping, the thickening population, or the high state of improvement of its banks, is wholly without parallel. The Severn, though not equal to the Tay in quantity of fresh water, is superior to the Thames, and during the first part of its course preserves the characteristics of a mountain stream, being clear, and at times bordered by picturesque scenery; but on leaving Wales, and entering a more level country, it assumes a different aspect, and becomes a full slow-flowing river, admitting of easy navigation, and facilitating greatly the commerce of Shropshire, Worcestershire, and Gloucestershire. Towards its mouth it receives the Wye, a large navigable river from Wales. The Trent rises in Staffordshire, and after a course, often tortuous, but generally in a north-east direction, falls into the Humber, which soon after becomes a broad estuary. The Mersey, as a river, is of no great importance, but as an arm of the sea it affords, from the west, a very capacious inlet to the trade of Liverpool, and facilitates the conveyance of the produce of the interior. The Tyne is a large stream, having Newcastle on its banks, and Shields near its mouth. The Medway, as a fresh-water river, is small and sluggish, but acquires, by the influx of the tide, such a depth of water at Chatham as to adapt it to the reception of the largest men of war. Speaking generally, it is only the rivers of Wales, Westmoreland, Cumberland, and a few mountainous districts, that are rapid or transparent; the great majority of English rivers, particularly in the eastern and central part of the kingdom, are slow in their course, and owe the degree of beauty which they possess, less to the effect of the water or scenery, than to the high cultivation and elegant disposition of the adjacent grounds.

Lakes and forests.

A similar remark applies to the lakes of England. Nothing can exceed the beauty of Winandermere, Keswick, and Ulleswater; whilst the unvaried and uninteresting collections of water, such as Whittleseameer, and others in the fen district, are to be compared only to those in North Holland or Friesland. In regard to wood, England is very well provided, without having many of those extensive forests which are met with on the Continent upon great mountain ranges, such as on the Jura ridge between France and Switzerland, and the Suabian Alps upon the Upper Rhine. It is in private plantations of limited extent, but of very frequent occurrence, and sometimes of great beauty, that the chief stock of English timber is to be found. Several very extensive tracts, such as the New Forest in Hampshire, the Forest of Dean in Gloucestershire, and Sherwood in Nottinghamshire, belong to the crown.

Soil and produce.

The soil of England is suited to a great variety of products; but it has not the exuberant fertility of southern climates, much labour and vigilance being requisite to obtain from it a grateful return. The quantity of moisture makes it admirably adapted for pasture; a characteristic which does not particularly strike those whose travels have never extended beyond their own country, but is of the highest importance in the view of those who have visited the Continent, and have witnessed the parched and arid state of the richest plains in the months of autumn. In regard to husbandry, it happens, by a singular coincidence, that in England, as in Scotland, the best is practised in the east part of the island, particularly in Norfolk and Northumberland. As to mineral treasures, the eastern counties of England, to the south of Yorkshire, are remarkable for containing no mines either of coal or of metal: these valuable deposits are to be sought in the more uneven districts of the north and west, viz. in Northumberland, Durham, Westmoreland, Lancashire, Shropshire, Worcestershire, Devon, and Cornwall, in Wales, and in the midland counties of Warwick, Stafford, and Derby. In the east, particularly in Lincoln and Cambridgeshire, vast improvements have been made in the present age by draining; but there are still the means of making further and valuable acquisitions. Much also remains to be done in bringing into culture extensive heaths and moorlands in almost every county in the kingdom. The soil of these is in general poor, but the tillage required would seldom be obstructed, as in many parts of Scotland, by the ruggedness of the surface. Comparing the soil of England with that of the adjacent countries, we find it greatly superior to that of Scotland, except along our eastern coast; it is perhaps better also than that of Ireland, fertile as the latter naturally is; nor needs it, on the whole, dread a comparison even with the soil of France, where, amidst districts of great beauty and luxuriance, the eye of the traveller is often struck with extensive tracts of heath or marsh.

The following table exhibits the area of each county in England and Wales, in acres and square miles, according to Arrowsmith's map. It also gives an estimate, 1*st*, of the extent of the arable, meadow, and pasture land in each county; 2*dly*, of the waste land in each capable of being converted into arable, meadow, and pasture; and, 3*dly*, of the extent of surface in each susceptible of cultivation, or of conversion into meadow or pasture, consisting of unimprovable mountain and moor, lakes, rivers, roads, canals, woods, fences, &c.

Counties.	Total Area in Square Miles.	Total Area in Statute Acres.	Arable Meadow and Pasture Land.	Waste Land capable of becoming Arable or Pasture.	Surface incapable of becoming Arable or Pasture.

ENGLAND AND WALES.					
Totals	57,960	37,094,400	28,749,000	3,984,000	4,361,400

This table, originally given in the Report of the Committee of the House of Commons on Emigration, was compiled by Mr Couling, civil engineer. It can of course only be regarded as an approximation; but as Mr Couling has bestowed great attention to the subject, we do not suppose that it involves any material error.

Climate.

The climate of England is that of an insular country of limited extent, subject in consequence to rain, and exempt from intensity of either heat or cold. Compared with the adjacent countries, it is less humid than Ireland, which, like Portugal, in a different latitude, is the first land to intercept the vapours of the Atlantic; but, on the other hand, the climate of England is less dry than the opposite shores of Holland and Germany, to which every wind but the west arrives across a tract of continent. The climate of the south of England resembles much that of the opposite coast of Brittany, Normandy, and Flanders; whilst that of the north is very similar to the temperature of Denmark, which, like the north of England, is a narrow country inclosed on either side by the sea. In regard to the relative degrees of heat or cold, if England have not so much summer warmth as continental countries on the same parallel, she generally escapes in winter that intensity of frost, which in less than forty-eight hours of easterly wind so frequently seals up their harbours. On the other hand, our weather is much more variable than in the inland part of the Continent, and our sky is less clear; still it by no means follows that the balance of disadvantage is on our side. The moderate heat and frequent returns of rain preserve throughout the year that verdant pasture which in autumn the Continent enjoys only in its maritime districts; whilst those droughts in spring, which are so noxious in the south of France and in similar latitudes of the Continent, are hardly known among us. In point of salubrity, also, we may fairly stand a comparison with our neighbours; for, variable as is our atmosphere, no country perhaps exhibits a larger proportion of examples of longevity.

There exists, however, a considerable difference in the climate of different parts of England. The west, exposed to the Atlantic, and containing hills and mountains which intercept the clouds, is much more rainy than the east, where the aspect of the country is level, and the expanse of adjacent water much less considerable. Another and equally remarkable difference arises from latitude, the season being a fortnight or three weeks later in the north than in the south of England. Notwithstanding all the skill of the Northumbrian farmers, the traveller who leaves the harvest finished in the south of England in the first week of September, and who sees the corn cut, if not carried, in the midland counties, will generally find it, in the middle of that month, untouched and standing in most parts of the country to the northward of York. In winter this difference in the temperature of the north and south of England is less perceptible. As to the spring months, March is proverbially raw and cold, from the prevalence of easterly winds, particularly in that part of the kingdom adjacent to the German Ocean. April is in general wet and favourable to vegetation; but May, though a pleasant month, can hardly be said with us to bring more " indulgent skies." It is in June, July, and August, that our climate assumes a more settled aspect; whilst, at the same time, the power of taking exercise on almost any day is indicative of a very gratifying advantage over the sultry atmosphere of our southern neighbours on the Continent. November, though frequently wet and foggy, is only a prelude to winter; even December does not often bring intense frost, which is commonly reserved for January; and during the last twenty years we have been repeatedly without any frost of consequence, or heavy falls of snow, until a considerable time after the days had lengthened.

Variations of temperature.

During the six winter months from October to March, the mean temperature of the central part of England is commonly between 42° and 43° of Fahrenheit. In December, January, and February, it is generally below 40°; in July and August 62° to 65°. The variations of temperature within the space of twenty-four hours are felt most strongly in the equinoctial months, March and September. In these there is often a difference of 18° or 20° between the day and the night, whilst in the summer months this difference seldom exceeds 12° or 15°, and in December or January is only from 6° to 8°. The mean annual temperature, noon and night, of the central part of England, is about 50°. The greatest summer heat seldom exceeds 80°, and the cold of December or January is rarely below 20° or 25°. In mild situations in Devonshire and Cornwall, the winter temperature is 2°, 3°, 4°, and even 5° higher than in London. Penzance is the spot in England least visited by severe cold; and it is consequently much recommended in pulmonary cases.

Of rain, the largest proportion falls in the north-west of England, particularly in Westmoreland and Lancashire, owing to the neighbourhood of the sea and the height of the mountains. There the average quantity is found to be forty-five, fifty, and, in some situations, sixty inches, whilst the average of the kingdom at large is from thirty to forty inches.

Prevaili winds.

The prevalent winds in England are west and southwest. Our outward-bound merchantmen are often detained, from the want of a northerly or easterly wind; but it rarely happens that our homeward bound are kept beating in the channel by the want of a westerly breeze. In these respects, also, the case is the same on the opposite shores of the Continent; the Dutch and French outward-bound vessels often experiencing detention from the continuance of westerly winds.

II.—*Divisions, Civil and Ecclesiastical.*

The civil divisions of England are those of counties, hundreds, and parishes. The county divisions, like several of our national improvements, date from the reign of Alfred, and, though subsequently increased by the acquisition of the three northern counties from the Scotch, have not, in other respects, experienced much alteration since his time.

Civil div sions.

The twelve counties of Wales added to the forty counties of England, make a total of fifty-two. The name of " county corporate" is given to most of the cities of England, and to some of the towns; and this distinction, little attended to by the public, and seldom mentioned but in law papers, implies that the district in question is governed by its own sheriffs and other magistrates, to the exclusion of the officers of the county at large.

The division into hundreds must have originated in reference to the existing population, and consequently implied a district containing either a hundred able-bodied men or a hundred families. As population increased very differently in different situations, great inequality ensued in regard to these divisions; and, in the reign of Henry VIII., many of the larger hundreds were partitioned into smaller districts. Hundreds were further subdivided in the time of Alfred into tithings, or associations of ten men, for the purpose of mutual defence. But both these subdivisions were unknown in the northern counties, from their not having been subject to the Saxon legislator: the latter, on their subsequent annexation to the crown of England, were divided into " wards" and " wapentakes;" terms sufficiently expressive of the warlike character of the age, and of the exposed situation of a frontier province.

Ecclesias tical div sions.

The ecclesiastical division of England is into two archbishoprics and twenty-four bishoprics. The archbishopric or " province" of York, though by much the smaller of the two, comprises Northumberland, Durham, Westmoreland, Cumberland, Cheshire, Lancashire, the chief part of Yorkshire, and the Isle of Man; and Canterbury extends over all the rest of the kingdom, including even Jersey and Guernsey. The bishoprics are very different in extent of jurisdiction, as well as in annual emolument. The third and most familiar of the ecclesiastical divisions of England is into parishes. This mode of division seems to have existed from a very remote period, and to have continued during the last five centuries on the same footing, with very slight variation, as at present. The total number of parishes in England and Wales is 10,674.

III.—*Harbours, Roads, Canals, Bridges.*

Harbours. Portsmouth, Milford Haven, and Plymouth, are the finest harbours in England, and are surpassed by few if any in the world. Of these, Portsmouth is entitled to the pre-eminence. This noble harbour is about as wide at its mouth as the Thames is at Westminster Bridge, expanding within into a capacious basin, almost sufficient to contain the whole navy of Great Britain. Its entrance is unobstructed by any bar or shallow; and it has throughout water adequate to float the largest man-of-war at the lowest tides. The anchorage ground is excellent, and it is entirely free from sunken rocks, sand-banks, or any similar obstructions. The western side of the harbour is formed by the island of Portsea; and on its south-western extremity, at the entrance to the harbour, is situated the town of Portsmouth, and its large and important suburb of Portsea. Here are docks and other establishments for the building, repair, and outfit of ships of war, constructed upon a very large scale, and furnished with every conveniency.

Portsmouth harbour has the additional and important advantage of opening into the celebrated road of Spithead, lying between the Hampshire coast and the Isle of Wight, and forming a safe and convenient retreat for the largest fleets.

Milford Haven deeply indents the southern part of Pembrokeshire. It is of great extent, and has within it many bays, creeks, and roads. The water is deep and the anchorage ground excellent; and being completely landlocked, ships lie as safely in it as if they were in dock.

Plymouth, which, after Portsmouth, is the principal naval depôt of England, has an admirable double harbour. The roadstead in Plymouth Sound has recently been much improved by the construction, at a vast expense, of a stupendous breakwater more than 1700 yards in length. This bulwark protects the ships lying inside from the effects of the heavy swell thrown into the Sound by southerly and south-easterly winds.

London stands at the head of the river ports of Great Britain. Considering the limited course of the Thames, there is probably no river that is navigable for large ships to so great a distance from the sea, or whose mouth is less obstructed by banks. London is mainly indebted for the unrivalled magnitude of her commerce to her favourable situation on this noble river; which not only gives her all the advantages of an excellent port, accessible at all times to the largest ships, but renders her the emporium of the extensive, rich, and populous country comprised in the basin of the Thames.

The Mersey, now the second commercial river in the empire, is more incommoded with banks than the Thames, and is in all respects inferior, as a channel of navigation, to the latter. Still, however, it gives to Liverpool very great advantages; and the new channel which has recently been discovered in the banks promises to be of much importance in facilitating the access to and from the port.

Bristol and Hull are both river ports. Owing to the extraordinary rise of the tide in the Bristol Channel, the former is accessible even to the largest ships. The Humber is a good deal impeded by banks; but it also is navigable as far as Hull by very large vessels. The Tyne admits vessels of very considerable burden as far as Newcastle, which, next to London, is the most important shipping port in the empire.

Roads. It was not until after 1660 that the public took an active part in regard to the highways. Turnpikes were at that time placed on the great North Road, in the counties of Hertford, Huntingdon, and Cambridge; but it was not till after the peace of 1748 that adequate exertions were made to redeem our public roads from their wretched condition. After 1760 the increasing price of agricultural produce, and the general spirit of improvement, had the most beneficial operation in this respect; and in the fourteen years from that time to 1774, no less than 452 acts were passed for the amelioration of our roads. It was then also that our inland navigation assumed an aspect of activity. The Bridgewater and Trent Canals were commenced; yet the number of canal acts which passed between 1760 and 1774 was only nineteen. The American war interfered considerably with public improvement; and it is only from the date of its cessation that we enter upon an active and prosperous era.

The total length of paved streets and paved roads in England and Wales may be taken, according to a parliamentary return in 1818, at about 20,000 miles; the total length of all other roads at nearly 96,000 miles. In France the highways are under the care of government, and are kept in repair out of the general taxes, without any tolls or turnpike dues; in England they are managed by the respective counties, represented by commissioners, and no part of the expense comes out of the public treasury. It is defrayed partly by local imposts, partly by dues levied; and the local impost is discharged either by labour or by composition money, thus:

The value of labour in kind (on an average of the years ending October 1812, 1813, and 1814) was	L.535,423
The average amount of composition money	278,506
The average amount of dues or rents levied	601,954
Annual average of the expenditure on the roads of England and Wales	L.1,415,883

being at the rate of nearly L.12. 6s. 8d. per mile. In the Highlands of Scotland, where the travelling is so much less, one third of this allowance is sufficient for the annual repair of the roads.

Canals. The canals of England are extremely numerous; in fact, no country except Holland can enter into competition with us in this respect. Amongst the principal are the Grand Junction, advancing from London above 100 miles into the midland counties; the Grand Trunk, extending from the Severn northward into Staffordshire, a distance of 139 miles; the Liverpool and Leeds, extending 130 miles; the Oxford, ninety-one miles. To proceed with the enumeration would be almost endless; suffice it to observe, that the English canals are of moderate size, being from twenty-five to thirty, thirty-five, and forty feet in width, and, in general, from five to six feet in depth; the barges navigating them are very long, frequently seventy or eighty feet, on a width of ten, twelve, or fourteen feet; but in many cases their dimensions, at least their width, are necessarily smaller, the less frequented canals being narrower than those we have mentioned. Could the application of steam to navigation have been foreseen, the canals of England would probably have been made wider. For full details with respect to the canals of England, and the recent improvements in their construction, and in travelling by them, the reader is referred to the article NAVIGATION INLAND.

Bridges. The principal bridges in the kingdom are the six erected across the Thames at London, three of which have been opened since 1817. Of these, two, the Southwark and Vauxhall, are of cast iron, the one being of three very large arches, and the other of nine arches, each of seventy-eight feet span. The first example of an iron bridge on a large scale, either in England or any other country, was that erected in 1796 at Wearmouth in Durham, the span of which was 240 feet. In the same year was finished at Buildwas, near Colebrook Dale, over the Severn, an iron bridge of 130 feet in span. See article BRIDGE, in this work.

IV.—*Agriculture.*

Of the state of English agriculture in former ages we can form some idea from a reference to the acts of the legislature. In these we find, at a very early date, the traces of that policy which expects abundance and cheapness to result from discouraging the exportation of corn. No permission to export seems to have been granted till 1394, and then only on the payment of certain duties; in 1436 some additional latitude was given, and exportation was allowed when the quarter of wheat did not exceed a price corresponding to nearly 13s. of our present money. The reign of Elizabeth was the epoch of a great rise in the prices of corn, originating, not, as was vulgarly asserted, in the "decay of tillage," but in the sudden depreciation of money, produced (as has been explained in the article CORN LAWS) partly by degradation of the coin, and partly by the influx of silver from the mines of America. The complaints of the "decay of tillage," if they express any thing more than the ordinary discontent of the ignorant part of the consumers, are to be accounted for by the gradual consolidation of small farms, and by inclosing land for pasture, with a view to the exportation of wool. In these days, however, government participated in the prejudices of the people; and the general purport of the acts passed under Elizabeth and her successors was to shackle exportation and prevent a rise of price. It was not till the reign of Charles II. (1670) that the exportation of corn was exempted from taxation; and it is from 1689 that we are to date that fundamental change in our corn laws which encouraged exportation by a bounty.

Clover, turnips, and potatoes were introduced into England in the seventeenth century. In the *Improver Improved*, published by Blythe in 1649, we find the first traces of what may be termed the modern system of husbandry; that is, of a rotation of crops, and of the occasional substitution of green for culmiferous crops. But the practice, though thus early introduced, and though it lies at the foundation of all good husbandry, made but little progress for a very long period. The writings and the example of the famous Jethro Tull, in the early part of last century, notwithstanding he carried his theory to an excess, did much to introduce the practice of drilling, and had a very favourable influence on agriculture. Nothing, however, did half so much to accelerate the march of improvement, as the wonderful increase of manufactures and commerce, and consequently of the town population, subsequently to the peace of Paris in 1763. The greater number, and still more the improved circumstances, of the people, occasioned, in particular, a very great increase in the demand for butchers' meat. And it is to this circumstance that we are mainly indebted for the extraordinary improvements which have been made during the last sixty or seventy years in stock husbandry. But the indirect influence of the augmented demand for butchers' meat has been equally conspicuous, and has proved of the utmost advantage to arable husbandry, inasmuch as it caused a corresponding increase in the demand for green food, that is, for turnips, clover, &c. This did incomparably more than anything else to introduce that intermixture of green and culmiferous crops which is so essential to good husbandry; and it was the real cause of the greatest of all agricultural improvements, namely, the substitution of turnips for fallows on all light lands. This has increased the productive power of the soil in a degree not easy to be conceived; and, coupled with the frequent substitution of beans for naked fallows on stiff clay lands, has in all probability more than doubled the available raw produce of the kingdom.

For a lengthened series of years England exported large quantities of corn. But notwithstanding the vast additions made to the supplies of corn by the improvements alluded to, the still greater increase of wealth and population, after occasioning, first a diminution, and next a cessation of exportation, has for many years past made the balance incline on the side of importation. It has been supposed by some that this change was owing to the alterations effected in the laws with respect to the importation of corn in 1772; but we have elsewhere shown that there is no room or ground for any such opinion. (See CORN LAWS AND CORN TRADE.) There cannot, indeed, be the shadow of a doubt that our having changed from being an exporting to an importing country, is entirely owing to the demand having shot a head of the supply, in despite of the wonderful increase of the latter. If doubt should remain in the mind of any one as to this being the real cause of the change, it would be removed by attending to the progress of the inclosure bills. The first act for effecting an inclosure was passed in the reign of Charles II. Since the revolution the progress has been as follows·

	Number of Acts passed.	Number of Acres inclosed.
In Queen Anne's reign	2	1,439
In George I.'s reign	16	17,660
In George II.'s reign	226	318,778
In George III.'s reign to 1797	1532	2,804,197

According to this statement, taken from the report of the committee on waste lands, it appears that each inclosure act passed during that period of the reign of George III. which terminated with 1797, inclosed at an average 1830 acres. Now it appears from the official returns, that from 1798 to 1833 both inclusive, 2103 inclosure acts had been passed; and supposing each to have inclosed, as before, 1830 acres, the total would amount to 3,848,490 acres, making, when added to the quantity inclosed previously to 1798, an aggregate of no less than 6,652,687 acres inclosed since 1760. But as it seems probable that the earlier acts would apply to a larger extent of land than the later ones, we may perhaps estimate the total extent of land inclosed and divided by act of parliament from 1760 to 1833 at from 5,500,000 to 5,800,000 acres. And it may be safely affirmed, that in consequence of its inclosure, the produce of this immense extent of land has been increased at least from *four* to *five* fold.

As might be expected, a decidedly greater number of inclosure acts were passed in 1802, and during the five years ending with 1814, when prices were enormously high, than in any other equal period of time.

Account of the Number of Inclosure Acts passed, and of the average Price of Wheat, in England and Wales, each Year from 1798 *to* 1833, *both inclusive.*

Years.	Acts.	Price of Wheat per Quarter.

1833	15			

Crops cultivated: extent of ground under cultivation.

The principal crops cultivated in England and Wales are wheat, oats and beans, barley and rye, turnips and potatoes, with clover, hops, flax, &c. It is to be regretted that no estimate has been formed on which much reliance can be placed, either of the extent of land under different crops, or of the average product per acre. Mr Middleton, in his *Survey of Middlesex* (vol. ii. p. 640), estimated the whole land under tillage in England and Wales at 12,000,000 acres; and Mr Comber, in his *Treatise on National Subsistence* (p. 52), estimated it at 11,591,000 acres. We incline to think that these estimates are not very wide of the mark as to the number of acres; but in both, the extent of land under wheat seems to be materially underrated, whilst that under fallow seems to be equally exaggerated. The following may, we believe, be regarded as a pretty fair estimate of the extent of land under the different species of crops, and in fallow, in England and Wales, on an average of the last half dozen years.

	Acres.
Wheat	3,800,000
Barley and rye	900,000
Oats and beans	3,000,000
Clover	1,300,000
Roots (turnips, potatoes, &c.)	1,200,000
Hops, gardens of all sorts, &c.	150,000
Fallow	1,650,000
	12,000,000

Quantity and value of crops.

In 1800 a committee of the House of Lords was appointed to inquire into the causes of the scarcity which then prevailed. Under the directions of this committee the board of agriculture circulated queries, and investigated with considerable minuteness the subject of the average productiveness of the different species of crops in the different countries of Great Britain. The result of these inquiries are given in the appendix to the Report of the Committee; and from these it appears that the average produce of wheat throughout England and Wales may be taken at from two and a half to three quarters (Winchester measure) per acre, barley at four quarters per ditto, oats four and a half, peas two and a half, beans three and a half, and potatoes at 250 bushels. We have, however, been assured that the wheat culture has since been so much improved, that making due allowance for the greater quantities produced in the best wheat counties, as Kent and Essex, the average produce may be safely reckoned at three quarters an acre; and taking these results, and the average prices of the last ten or twelve years, we get the quantity and value of the principal crops as follows:

Crops.	Acres.	Produce per Acre. Quarters.	Total Produce. Quarters.	Price per Quarter.	Value.
				s.	*L.*
Wheat	3,800,000	3	11,400,000	60	34,200,000
Barley and rye	900,000	4	3,600,000	30	5,400,000
Oats and beans	3,000,000	4½	13,500,000	25	16,875,000
Roots	1,200,000	£5 5 0 per acre.			13,125,000
Clover	1,300,000				
Totals,			28,500,000		69,600,000

The oats and beans are here blended together and reckoned at the price of oats; whereas beans are about 10s. a quarter higher. Allowing for this, the two may be worth together L.17,500 000. The grounds occupied as gardens, hop-plantations, &c. may produce, at an average, about L.15 an acre, or L.2,250,000 a year; making the total value of the different crops raised in England and Wales L.72,475,000.

Expense of cultivation.

Attempts have frequently been made to estimate the expenses attending the cultivation of land at different periods; but we have not seen any statement of the sort on which we should be disposed to place much reliance. A good deal of the expense is of a very fluctuating nature, depending on the prices of grain and stock, the rate of wages, amount of capital employed and interest thereon, rent, public burdens, &c. It may probably be considered, and taking all things into account, that the expenses of cultivation in England and Wales are at this moment about thirty per cent. higher than in 1792.

Cattle and sheep, &c. Owing to the improvements in the breed and in the feeding of cattle, the weight of those now annually slaughtered has increased from a third to a half above what it is stated by Dr Davenant to have been at the beginning of last century. Various discordant estimates have been formed of the number of cattle in England and Wales; but the best authorities seem to think that they may amount to 4,000,000 or 4,500,000.

Horses. Horses are of course far less numerous than cattle, and are proved by the tax returns not to exceed 1,400,000 or 1,500,000. (See M'Culloch's *Commercial Dictionary*, art. *Horses.*)

Sheep. According to the elaborate tables of Mr Luccock, revised by Mr Hubbard, there appears to be in England and Wales nearly 15,000,000 of short, and rather more than 4,000,000 of long woolled sheep, with about 7,000,000 lambs. The weight and value of the fleece varies very much according to breed, keep, &c. But, at an average, the weight of the fleeces of short-woolled sheep may be taken at from three to four pounds, and those of the long-woolled at from seven to nine pounds. The total quantity of wool annually produced in England and Wales is estimated by the same gentlemen at 385,000 packs, of 240 pounds each. Merinos were introduced about the beginning of the present century, and were imported in large numbers after our alliance with Spain in 1809. Opinions differ in regard to their utility, the carcass not having answered so well as the fleece. Considerable advantage, however, has been derived from crossing them with our own breeds, and further experience may lead to more beneficial results.

The great pasturage counties are Leicester, Northampton, Lincoln, and Somerset. Of the counties producing butter and cheese, the principal are Cheshire, Gloucestershire, and Wiltshire. But notwithstanding the immense supplies of these articles produced at home, the demand is such, that at an average we import about 130,000 cwts. a year of foreign butter, and about an equal quantity of cheese, principally from Holland. The average annual importation of Irish butter into England cannot be precisely ascertained; but in 1825 it amounted to 425,000 cwts. and may now (1834) be taken at 500,000.

Produce of grass-lands. The produce of grass-lands may be determined in two ways; either by ascertaining the quantity and value of the different articles annually produced, or by taking a general rough average value per acre. The former would be the most satisfactory mode; but the details are too numerous and too loose to admit of their being put forward with much confidence. We believe, however, that the annual value of the various products derived from pasture-land may be estimated, on an average, at about L.3. 10s. an acre; being equivalent, upon 17,000,000 acres, to L.59,500,000.

This sum of L.59,500,000 consists, probably, of the following items:—

Cattle 1,000,000, at L.20 each	L.20,000,000
Calves 200,000, at L.3	600,000
Sheep and lambs 6,800,000, at L.1. 10s.	10,200,000
Wool (exclusive of slaughtered sheep) 338,000 packs, at L.12	4,056,000
Hogs and pigs 450,000, at L.1. 10s.	675,000
Horses 200,000, full grown, annually produced	3,000,000
Poultry, eggs, rabbits, &c.	1,000,000
Meadow and grass for work and pleasure horses	10,000,000
Dairy produce, or milk, butter, and cheese	9,969,000
	L.59,500,000

The total annual value of the agricultural produce of England and Wales may, therefore, be estimated at about L.132,000,000 (L.72,475,000 + L.59,500,000).

Rent. The rent of land in England and Wales is usually estimated at from one fifth to one fourth of the value of the produce, which, taking the latter at L.130,000,000, would give from L.26,000,000 to L.32,500,000, or L.29,250,000 at an average, as the rent of the kingdom. We incline to think that this is pretty near the real amount. In 1810 the rent of England and Wales, as ascertained by the property-tax commissioners, was L.29,500,673; and the general opinion amongst persons well informed as to such matters seems to be, that the rent at present is about equal to the rent in 1810; the rise that took place in the four succeeding years having been balanced by the fall that has taken place since.

Farmers capital, profits, The capital employed in the cultivation and stocking of the land in England cannot be estimated, at the present prices, at less than from L.6 to L.7 an acre; which, excluding waste land, would give a total capital of from L.172,494,000 to L.201,243,000. It appears from the property-tax returns for 1810, that the profits made by the occupiers were almost identical with the rent. But it will be observed, that, besides the interest on, or return for, the capital employed in farming, the profits in question included all that the occupiers received on account of their trouble in superintendence, and for the greater part of their own labour and that of their families.

Size of farms. We have already, in the article AGRICULTURE, treated of the points of superiority in our husbandry over that of the Continent; ascribing it to various causes, and to none more than the medium size of our farms, which differ equally from the large unmanageable tracts held by Polish noblemen, and the diminutive occupancies so common amongst the French peasantry, particularly since the Revolution.

The size of farms in England is greatest in the best cultivated districts, that is, in the counties to the east of the metropolis, viz. Kent, Essex, Suffolk, and Norfolk. Farms are also extensive in Northumberland. In these counties the engagements of farmers are for larger sums than in East Lothian, Berwickshire, or any part of Scotland, rents being frequently from L.800 to L.1200 and L.1500 a year. In more retired districts, particularly in Cumberland, Westmoreland, and Wales, the occupancies, whether farmed or held in property, are in general very small; and an average of all the farms of England and Wales would not much exceed L.150 a year.

Leases. Leases in England are, with the exception of particular districts, granted for seven years only; when the term is longer the case is peculiar, and applies to land which evidently requires very extensive improvement. But by far the largest portion of England is held by tenants at will, or by tenants holding only from year to year. There is in such cases something like an assurance, on the part of the landlord, that the tenant shall not be removed for a certain number of years, or that otherwise the improvements shall be considered and allowed for. When a tenant holds from year to year there is a written agreement, with specified covenants, the tenant being subjected to fines in the event of a deviation from them. Both methods are highly injudicious; and it is in the prevalence of these, more than in the existence of tithes and poor's rates, that we are to look for the backward state of agriculture in many of our finest counties. No class of men have more liberality than the English landholders; but it would be in vain to expect a tenant to lay out much capital on the improvement of a farm of which his tenure comes to an end in seven years, or may be disturbed by the commission of a trespass or the occurrence of a death.

A tenant so situated loses the habit of reflecting on improvements, and even of carrying into effect those which he is aware would in time be advantageous. If he succeed in saving money, he is much more likely to place it out at interest than to employ it in his own business.

Compari- son with Scotland and the Continent.

In Scotland the rent bears a higher proportion to the gross produce than in England, being in general not less than from one fourth to one third. This is owing not certainly to greater capital, and still less to superior soil, but to an exemption from tithe and poor's rate, the use of long leases, and partly, and principally, we believe, to greater economy, particularly in the number of and expenditure upon horses. It is in tillage, not in pasturage, that the Scotch farmers lay claim to superiority. On comparing English agriculture with that of the Continent, we find that our chief superiority consists in machinery and in live stock. Thrashing machines are in a manner unknown on the Continent, and all iron manufacture is of inferior quality. In regard to live stock, the countries which approach nearest to us are Jutland, Holstein, Holland, Flanders, and Normandy, all evidently indebted for their extensive pasturages to the vicinity of the sea; in the interior of the Continent, pasturage is, in general, very indifferent. Even in these maritime provinces, the cattle, though frequently large, are not fattened in the same gradual manner as in our grazing counties; and the meat, consequently, is not of equal flavour. In horses the inferiority is more apparent to the eye, and holds both as to size and shape. Flemish horses are large, but heavy; whilst the Norman breed, though capable of much labour, is small in size when compared with the English. Nowhere are horses seen of such bulk and strength as the drays in London. If they are, as is supposed, of foreign origin, they have greatly surpassed the primitive stock, since neither the Netherlands nor Holstein can now match them.

We cannot close this part of our subject without a few remarks on the connection between the state of our agriculture and the extent of our financial burdens. Those who compare the heavy pressure of our taxes with the lighter burdens of our continental neighbours, have in general the satisfaction of finding some counterpoise in the superior dexterity of our people, and the productiveness of our capital. This holds true in regard to our navigators, our merchants, and our manufacturers; and it holds in agriculture in regard to grazing, because in grazing little personal labour is requisite, whilst capital and active habits of business are of the most beneficial operation. But, in the department of tillage, much remains to be done ere England can claim any great superiority. Farms are yet too small in more than two thirds of England, and leases are generally too short. The course of husbandry is frequently injudicious, the ploughs are on a bad construction, and there exists a gross misapplication of animal strength. However light the soil, and however strong the horses, it is still customary to put three, four, and frequently five, in a plough, throughout almost all the west and south-west counties. These are the main causes of the comparative unproductiveness of our finest counties, and of our being obliged to pay so heavy a premium in the shape of corn laws to support our agriculture. Without the corn laws, our lower classes would be supported on nearly the same terms as their continental neighbours; and there would be no occasion, with all our taxes, to dread the competition of foreigners in almost any branch of industry; but if the manufacturers of England are obliged to pay for their support thirty per cent. more than those of France and Germany, whilst their wages are very little higher, what other prospect have we than that of increasing emigration and the augmentation of the poor's rates?

The quantity of land still remaining uncultivated in the shape of wastes and commons is a frequent topic of animadversion; persons unacquainted with agricultural calculation calling loudly for this island being brought into culture, whilst the landed interest object to passing a general inclosure act, or, in other words, to giving unlimited scope to speculative cultivation. We by no means participate in the apprehensions of the latter; but we would abstain from giving any artificial stimulus to this, more than to any other branch of industry. Let the progress of inclosure be regulated by the gradual increase of our population, and the discovery of better methods of turning such land to account. No benefit can be derived from applying to this purpose any more capital than would go to it voluntarily; and every experienced farmer is aware, that the best prospect of profit lies, not in reclaiming new soils, but in bestowing further labour and expense upon the land already under culture.

V.—*Mines—Quarries—Iron, Copper, Tin, and Salt Works.*

In regard to minerals, England does not yield to any country in Europe in natural abundance, and takes the lead of all in the extent to which these rude treasures have been converted to purposes of utility. Our great superiority lies in our coal-mines, which are not only more productive, but much more advantageously situated, than those of the Continent. To the mines along the coast a ready conveyance is afforded by our insular position, and to those in the interior by our inland navigation. The consumption of coal in England for domestic use has been estimated at 20,000,000 tons annually. Large as this quantity is, and larger as it must be when we add to it the vast consumption of manufactories, such as iron-works, copper-works, salt-works, glass-houses, and the like, there is no reason to apprehend the exhaustion of this precious mineral; the depth of the coal beds being very great, and the extent of ground containing them amounting to many hundred thousand acres. The principal coal-beds lie in Northumberland, Durham, Derbyshire, Staffordshire, and Glamorganshire. The ports for shipping coal in large quantities are Newcastle, Sunderland, Swansea, and Whitehaven. The motive of the tax on coal exported to foreign countries is thus neither an apprehension of eventual scarcity, nor even a calculation of revenue, so much as a dread of giving our continental neighbours the means of rivalling our manufactures. Coal is not wanting in France and Germany, but the mines are at a distance from water carriage, and as yet very imperfectly wrought · whilst for the purpose of domestic fuel the inhabitants give a preference to wood.

A material advantage was conferred on the coal trade, and on all the southern parts of the empire, by the late abolition of the tax of six shillings a chaldron on all sea-borne coal. Mr M'Culloch, founding upon the calculations of Mr Ruddle and other eminent practical authorities, estimates the total number of persons engaged in the coal trade at from 160,000 to 180,000. (*Commercial Dictionary*, art. *Coal.*) The conveyance of coal from the Tyne and the Wear to London, and other southern counties, constitutes by far the most important part of the foreign trade of the empire.

In 1832 the exports of coal to foreign countries amounted to 588,446 tons, of the real or declared value of L.228,615, producing a revenue of L.56,706. We subjoin an account of the quantity of coal brought coastwise and by inland navigation into the port of London in 1831 and 1832, specifying the ships employed and the quantities furnished by each of the shipping ports:—

Ships.		Ports whence Shipped.	Tons.	
1831.	1832.		1831.	1832.
3845	3627	From the port of Newcastle	1,151,851	1,171,227
2041	2145	From the port of Sunderland	561,234	600,217
337	783	From the port of Stockton	62,749	172,930
223	190	From the ports of Blythe and Seaton Sluice	59,862	48,938
167	199	From Leith, Inverkeithing, Kirkaldy, and other ports in Scotland	39,337	49,579
121	195	From Swansea, Llanelly, Milford, and other places in Wales	26,302	45,065
272	389	From Hull, Goole, Gainsbro', and other places in Yorkshire	43,957	51,122
		Quantity which passed the Boundary Stones on the Grand Junction Canal at Grove Park, Herts, and on the River Thames, at Staines	8,381	10,742
7006	7528		2,053,673	2,149,820

Quarries.

In quarries, whether of stone or slate, England is not rich, particularly the eastern half of the kingdom; and hence the almost universal use of brick in ordinary buildings. It is not till the traveller reaches Durham that he finds stone commonly used. In the northern counties quarries occur frequently; in the southern, those of Portland and Bath are the most considerable. Still the annual profits of the whole are small when contrasted with the product of our mines.

Iron mines and works.

No branch of our industry has increased more rapidly in the present age than our iron-works. A century ago it was computed that we required an annual importation of 20,000 tons of foreign iron; an importation which for many years seems to have been on the increase, so as, after the middle of last century, to carry the quantity required to 30,000, 40,000, and even to 50,000 tons. This supply was brought to us from Sweden and Russia, and, though burdened with duty, it was in quantity more than double our native produce. But fortunately, after the year 1780, discoveries were made which increased greatly our supply at home. Bar iron had been manufactured in England, as on the Continent, with charcoal fuel only, coal being deemed inapplicable to that purpose. Under that impression, the rapid consumption of the wood in the neighbourhood of our different iron-works had necessitated a removal, at a great expense, of materials from one spot to another, and was on the point of causing an alarming decay in the business, when our iron-masters, after long perseverance, succeeded in applying coal to their manufacture. They had to contend with various prejudices, particularly the supposed inferiority of iron so made; but, in the course of years, the manufacture acquired such an extent that there were, in 1805, two hundred and twenty blast-furnaces, making 250,000 tons of pig iron.

The transition from war to peace did a good deal of injury to some branches of the iron trade; but the effect of the change was not of long duration, and the production of iron has since been astonishingly increased. In 1820 the produce was calculated at 400,000 tons. The excitement and speculation of 1824 and 1825 had a wonderful influence on this department. According to careful inquiries made at the time, the furnaces at work in England and Wales in 1827, with their produce, were as under:

Staffordshire	95 furnaces	216,000 tons.
Shropshire	31	78,000
South Wales	90	272,000
North Wales	12	24,000
Yorkshire	24	43,000
Derbyshire	14	20,500
Totals	266	653,500

Owing to the failure of various rail-road and other projects set on foot in 1825 and 1826, the supply of iron seems to have greatly exceeded the demand; and there was a very heavy fall of prices in 1828, 1829, and 1830. But within the last two years prices have again risen to more than their former level; and the iron trade is at this moment in a state of great activity. The produce of the various furnaces of England and Wales may be estimated at 650,000 tons, worth at an average L.6. 10s. a ton, making a grand total of L.4,225,000. For more ample details, the reader is referred to the article IRON.

Copper-mines have long been known in England, but they were wrought with very little skill or effect until towards the year 1700. Even at that time the annual produce, after smelting the metal from the ore, was only a few hundred tons of copper; and it hardly exceeded 1000 tons annually down to the middle of last century. From that time forwards the increase became considerable, as well in Cornwall as in Devon, North Wales, and Derbyshire; in all of which copper-mines were discovered and wrought. In North Wales there were two mines, Parys and Mona, which, for some time after the year 1780, yielded annually a large quantity of ore, but they are no longer so productive: the mines of Devon and Derbyshire continue to be wrought, but the great product is from Cornwall, the mines of which yield 145,000 tons of ore annually; the metal obtained, varying from five to fifteen in the hundred parts, may be stated at 12,000 tons of copper. It is the Welsh collieries which afford to Cornwall, as to Devonshire, the means of smelting; and as the ore is less heavy than the coal required for this operation (one ton of ore requiring from two to two and a half tons of coal), the practice is to convey the ore in vast quantities to Wales, particularly to Swansea. The total quantity of coal consumed for this purpose at Swansea is nearly 350,000 tons a year, exclusive of a further consumption of coal at the copper-mines of Cornwall, in working the ponderous steam-engines used in throwing out the water from the pits. In this, as in other minerals, France is greatly behind England. She has various copper-mines, but her coal-mines, at least those hitherto wrought, are at too great a distance to make such undertakings profitable; and she consequently requires an annual importation from England.

The entire produce of the copper-mines of England and Wales is at present about 14,000 tons a year of pure metal; and taking the price at L.100 a ton, its aggregate value will be L.1,400,000.

In 1831 there were exported brass and copper manufactures of the value of L.803,124, of which India, China, atistics.

and Ceylon took L.348,045, the United States L.169,533, France L.91,580, &c.

Tin.

Cornwall is also the great seat of the tin-mines of England. A century ago the average produce of our tin mines hardly exceeded.............................1500 tons.

From 1720 to 1740 the average produce was	2100
1740 to 1760	2570
1760 to 1780	2740
1780 to 1800	3100
1826 to 1829	4677

The produce of the mines at present does not materially differ from the last of these averages. From abroad we receive tin from one quarter only, viz. the East Indies, in particular from the island of Banca. Of this we imported, in 1831, 776 tons, the chief part of which was re-exported to the Continent of Europe. Of our own tin, about the half is used at home, and the other half finds its way to foreign countries, particularly Russia, France, and Italy.

Lead.

The lead-mines of England are principally in Cumberland, Northumberland, and Derbyshire; the whole being calculated to produce from 12,000 to 15,000 tons annually. Black lead is found in abundance in Cumberland, in the romantic district of Borrowdale; but the mine is opened only periodically, in order that the market may not be overstocked.

Salt.

Salt is already a very important product in England, and is likely to become much more so from the measures urged of late years on the legislature, part of which have been adopted, whilst a further part seems only to wait a season of less financial pressure. (*Report of Committee on the Salt Duties*, June 1818.) Salt is obtained in several ways; partly from brine springs, partly from the rock, partly from sea water. In the last manner it is manufactured in various salt-pans along the coast, viz. in Hampshire, Kent, and Essex; also in the northern counties of Durham and Northumberland, where the abundance of coal reduces materially the expense of the process. But the great supply is from the rock salt and brine springs of Cheshire, situated in the southern part of the county, near Northwich. From these springs it is obtained (see the article Cheshire) at the rate of one gallon of solid salt from four gallons of liquid, whilst common sea water does not yield above one in twenty-eight. The consumption of salt in this country is immense. Necker estimated its consumption in those provinces of France which had purchased an exemption from the gabelle (*pays francs redimées*) at about 19½ lbs. (Eng.) for each individual. (*Administration des Finances*, tome ii. p. 12.) From all that we have been able to learn on the subject, we believe that the consumption of the people of this country may be estimated a little higher, or at 22 lbs.; the difference in our food and habits, as compared with those of the French, fully accounting for this increased allowance. On this supposition, and taking the population at 16,000,000, the entire consumption will amount to 352,000,000, or 144,200 tons.

Exclusive of this immense home consumption, we annually export about 10,000,000 bushels, which, at 56 lbs. a bushel, are equivalent to 250,000 tons. The Americans are the largest consumers of British salt, the exports to the United States in 1829 having amounted to 3,515,924 bushels. During the same year we exported to the Netherlands 1,583,517 bushels, to the British North American colonies 1,472,000 ditto, to Russia 1,388,490 ditto, to Prussia 949,834 ditto, &c.

The cheapness of this important necessary of life is not less remarkable than its diffusion. Its present cost may be estimated, at a medium, at from 14s. to 16s. a ton.

Salt has been at all times a favourite subject of taxation. In this country it was first taxed in the reign of William III. In 1798 the duties amounted to 5s. a bushel, but they were subsequently increased to 15s. a bushel, or about forty times the cost of the salt. So exorbitant a duty was productive of the worst effects, and, in particular, occasioned a great deal of smuggling. The duty having in consequence become exceedingly unpopular, was finally repealed in 1823.

Statistics.

VI.—*Fisheries.*

A season of peace is always favourable to the extension of our fisheries; and, if we may judge from the progress lately made, this branch of our national industry is likely to be carried further than at any former period of our history. Of this we shall treat more fully under the article Fishery. At present our space allows no more than a brief notice of the principal branches of our fisheries.

Mackerel.

The mackerel fishery is strictly English, and is carried on with great vigour on the coasts of Kent and Sussex, in May, June, and July. Large as the supply is, it would still admit of augmentation; and herrings also might be caught in vast quantities on the coast of Kent in October and November. The desideratum with the fishermen, now that peace has reduced their expense, is not so much a high price as a certain market; and the most effectual way to procure that is, to quicken, by every possible means, the conveyance to London, which has been accomplished by the employment of steam-boats. The conveyance of fish by land-carriage from Brighton, and other parts of the Sussex coast, to London, has also been accomplished by improvements in the roads.

Pilchards.

The pilchard fishery takes place chiefly on the coast of Devonshire and Cornwall, and, though subject to great fluctuations, as well from the seasons as from our political situation relatively to the Continent, forms on the whole an important branch, employing a number of seamen both in catching the fish and in carrying it to foreign markets. Its season is generally from June to September.

Herrings.

The herring, the most important of all our fisheries, is happily now in a state of rapid extension. It formed, during the seventeenth century, the great employment of the Dutch seamen, and was contemplated by their neighbours with very jealous eyes. Accordingly, in the reign of Charles II., particularly after the rupture with Holland in 1672, several acts were passed for the encouragement of our fishermen, and in a spirit of hostility to the Dutch. The subsequent accession of William to our throne, and the long friendship between the two countries, relaxed the exertions of government; and it was not till after the peace of 1748 that a large bounty was given on the tonnage of the busses, or masted vessels, so employed. Still our fishermen proved unable to compete with the experience and patient perseverance of the Dutch, and it was found necessary to raise the bounty from 30s. to 50s. per ton. This had the desired effect, and the number of busses increased; but the additional 20s. being withdrawn in 1771, the fishery again declined. The American war, and, subsequently, the wars of the French revolution, proved extremely adverse to its extension. At last, in 1808, an act was passed carrying the bounty to L.3 a ton on the busses, with a further grant of 2s. per barrel on all herrings caught, whether in busses or boats. This act was further confirmed in 1815, and the bounty per barrel raised to 4s. with the qualification that the herrings should be gutted before curing.

In consequence of the encouragement thus afforded, the fishery was materially extended; but this was effected at a great expense, and had, besides, several bad consequences. The bounties given by government tempted persons without capital or skill to enter into the business, to the great injury of the regular fishermen; so that notwithstanding the extension of the business, it was found, as is invariably the case with all departments carried on by means of a bounty, to be in a very unhealthy state. In consequence partly of the circumstances now stated, and partly in consideration of the real and substantial relief given to the fishery by the abolition of the duties on salt, it was resolved gradually to withdraw the bounty, which totally ceased in 1830. And we are happy to have to state, that though the fishery fell off whilst the bounty was in the course of being withdrawn, it has since been materially increased, and is now in a better situation than at any former period.

The curing of herring in Scotland is still subjected to the supervision of a public board; but we are not aware that its interference has been or can be productive of any good effect; and it will, we hope, be dispensed with.

Account of the Quantity of Herrings Cured, Branded for Bounty, and Exported, from 1811 *to* 1831 *both inclusive.*

Years ending 5th April.	Total Quantity of Herrings Cured.			Total Quantity of Herrings Branded for Bounty.	Total Quantity of Herrings Exported.

Whale fishery.

Greenland was first discovered by the English; but in this, as in other branches of navigation, we long allowed the Dutch to take a lead. It was not till after 1750 that, government having granted a bounty of 40s. a ton on every vessel employed in the whale fishery, a considerable increase took place in this branch.

In 1750, the vessels employed were only nineteen; in 1756 they had increased to sixty-seven. The war soon caused a decrease of one half; but at the return of peace in 1763 this fishery revived, and in 1770 the vessels employed amounted to fifty, in 1773 to fifty-five, in 1775 to ninety-six. The American war again caused a decrease, and in 1782 the vessels so employed were only thirty eight. In 1784 they increased to eighty-nine, and in 1785 to 140. After this they exceeded 200 annually till 1793; but the long continuance of the late wars reduced them below the half, and the advantages of peace have been counteracted by causes which have as yet prevented the English vessels from regaining the number employed previously to 1793. In 1832, the whale fishery employed thirty-nine English and forty-two Scotch ships, of the aggregate burden of 26,393 tons.

The Newfoundland fishery has been considerable for fully a century past. As a nursery for seamen, it is accounted of such consequence as to have formed the object of a specific article in most of our treaties of peace. The fish caught, particularly in time of peace, is sent less to Britain than to the Catholic countries in the south of Europe; a market subject to all the interruptions attendant on a change of political relations. The number of vessels employed in this fishery at different times was as follows:

In 1731.. 70
1764..140
1774..254

The American war caused a diminution; but in
1784 the number was........................236
1785..292

At this rate the fishery continued until the war of 1793, after which, particularly after our rupture with Spain in 1797, it fell off greatly; the fishing vessels in 1798 being only 140.

The continuance of war, and the aggrandisement of the French in Italy, occasioned additional depression; so that in 1810 the number of our vessels employed at Newfoundland did not exceed ninety-two. The peace seemed to promise a revival of this important nursery of seamen; and in the year 1816 the number of vessels which arrived in Newfoundland was 795, manned by 6000 seamen (*Report of Committee* in June 1817, p. 7); but the trade, both then and in 1817 and 1818, proved unprofitable, in consequence of indifferent seasons, of the high duty imposed on fish imported in British vessels into Naples, and of the competition of the French fishermen, supported by a high bounty from their government. Of late years very few British ships have gone to the Banks; but we carry on an extensive fishing along the coast of Labrador, and on the shores of Newfoundland. But the more convenient situation of the New Englanders, who are very expert fishermen, give them advantages with which the British find it very difficult to contend; and, partly from this cause, and partly from the forcing system of the French, and the greater duties laid on the importation of salted fish into most Catholic countries, the business appears to be rather in a depressed state. Mr M'Gregor estimates the total produce of the British fisheries in the seas and islands of America, on an average of the five years ending with 1832, at L.857,210 a year.

It is matter of surprise to foreigners that a maritime nation should not have more effectually cultivated this great means of facilitating the support of our population. The ample supply which might have been afforded by the Nymph Bank, on the south-east coast of Ireland, has been avowedly neglected; and it was only in 1818 that we made the discovery of a bank of almost equal productiveness in the vicinity of Orkney. Fish is little known to the mass of the people in our inland counties. Whilst the value of butcher's meat annually consumed in England exceeds L.30,000,000 sterling, the value of the fish caught upon our coasts and in our rivers hardly exceeds L.2,000,000. Yet its price, with the economy and improved arrangements attendant on a state of peace, would not exceed 20s. a cwt., whilst other animal food costs more than twice that sum. But the truth is, that fish has never been a favourite article of food with the bulk of the English people; and, notwithstanding all that has been said to the contrary, we are by no means satisfied that they would gain materially by a change in this respect.

VII.—*Manufactures.*

Voollen manufac-ory.

In this great department of our productive industry we begin with woollens, which, although no longer the largest of our manufactures in point of exportation, nor even in the value annually made, is entitled to the first place from the priority of its establishment, as well as from the substantial basis on which it rests. England, from the extent of her pastures, abounded in wool from a very remote age, and the inhabitants were doubtless capable of manufacturing it into rude clothing; each weaver working in his separate cottage, and with very little aid from machinery. In the twelfth and thirteenth centuries we appear to have had only the most humble fabrics, and to have imported all cloth of finer texture; sending abroad our wool in quantities to Flanders, a country the inhabitants of which were at that period much further advanced than the rest of Europe, with the exception of Italy. It was in the middle of the fourteenth century that a better system was introduced. Flemish manufacturers were invited over to England, and improved greatly the quality of our home-made woollens. The seats of this branch of industry appear at that time to have been Kent and Essex; afterwards Gloucestershire, and subsequently the West Riding of Yorkshire. It occupied at first the southern and more improved districts, and spread afterwards to the northward, on account of the cheapness of labour, the abundance of coal, and the convenience of waterfalls for the machinery. The general character of the woollen manufacture of England has been that of slow progress, but of little fluctuation; the latter evidently a consequence of its depending more on home consumption than on exportation. In the long period from 1700 to 1780, the exports experienced a regular but not rapid rise, amounting in the latter years to about L.3,500,000, whilst our home consumption increased in proportion to our augmenting numbers. More recently the manufacture has been materially improved by the adoption of various important mechanical inventions in the spinning, weaving, and dressing departments. On the whole, however, improvement has been much less rapid in it than in the cotton manufacture; so that whilst our exports of cotton stuffs and yarn have increased beyond all precedent, those of woollens have been comparatively stationary.

As we shall enter fully, in the article WOOLLEN MANUFACTURE, into the details connected with its history, progress, and present state, it would be useless, even if our limits permitted, to anticipate these here. We shall only observe, therefore, that the entire value of the manufacture is estimated by the best authorities at L.18,000,000, which is believed to be distributed nearly as follows:

Raw material (wool)	L.6,000,000
Oil, dye-stuffs, soap, &c.	1,200,000
Wear and tear of capital and profit	3,500,000
Wages	7,300,000
Total	L.18,000,000

Now, supposing that each person, young and old, male and female, engaged in the manufacture, earns, at an average, L.20 a year, the total number employed will be 365,000.

By far the largest proportion of the raw material of the manufacture is the produce of our own flocks; but for many years past, and especially since the peace, we have imported large quantities of wool, principally from Germany. The subjoined accounts give a full view of the state of the foreign woollen trade in 1831, the last year for which the details have been published.

Imports of Wool.—During the year 1831 we imported 31,652,029 lbs. of wool, of which 22,437,022 lbs. came from Germany, 3,474,823 lbs. from Spain, 2,493,337 lbs. from New South Wales and Van Diemen's Land, with smaller quantities from France, Portugal, Prussia, &c.

For an account of the prices and qualities of wool, &c. the reader is referred to article WOOL in this work, or in M'Culloch's *Commercial Dictionary.*

Our cotton manufacture is entitled to the greatest attention on different accounts. Of all our manufactures, it affords the largest export, and exhibits the most rapid improvements in machinery. Its introduction, though not remote, is less recent than is commonly supposed. It appears to have taken place about two centuries ago, when it was established at Manchester; but it was long conducted upon a very limited scale. The raw material, imported at first only from the Levant, in particular from Smyrna, began, after 1660, to be supplied by our West India colonies. The quantity imported amounted, about the year 1700, to 3500 bales; but, increasing with the extended cultivation of our colonies, it averaged, about the year 1720, something more than 7000 bales. From the colonial conquests of the war of 1756, our import of cotton received a further augmentation; but the manufacture increased very slowly, a great part of our cotton being re-exported to Holland, for the supply of Dutch and German weavers. It was not till after the peace of 1763, and the invention, first of the carding machine, and next of the spinning jenny, that this manufacture became considerably extended. In 1775, the average import of cotton approached to 18,000 bales. A variety of inventions, unequalled in the history of manufacturing industry, were now made (see our article on the COTTON MANUFACTURE), which gave an astonishing stimulus to the business. Fine calicoes and muslins were introduced; the workmen were withdrawn from their detached dwellings, and collected into large factories, and the price of the finished article experienced a reduction, notwithstanding a rise in the raw material, and in the wages of labour. The period which followed the peace of 1783 is perhaps unexampled for the reduction of price and the consequent extension of sale that took place in regard to cotton goods. The commencement of hostilities in 1793 gave a pretty severe shock to the business; but the improvements in machinery continuing, the manufacture soon recovered, and has gone on increasing, under many vicissitudes, with a rapidity unparalleled by any other business, either in this or any other country. Neither does there seem to be any ground for fearing that this progress will be speedily checked. On the contrary, our superiority in all that contributes to the advancement of the manufacture is so very decided, that, provided the public tranquillity be preserved unimpaired, we have nothing to fear from the competition of others.

The reader is referred to the article COTTON MANUFACTURE in this work for an account of the rise and progress of this great branch of national industry. But the following tabular statements are interesting, as exhibiting the present magnitude and importance of the trade, the sources whence the raw cotton is derived, and the foreign markets for the finished articles.

Mr M'Culloch gives, in the second edition of his *Dictionary*, the following estimate of the total value of the cotton manufacture of Great Britain, and of the amount of capital, and the number of persons employed in it.

Total value of every description of cotton goods annually manufactured in Great Britain		L.34,000,000
Raw material, 240,000,000 lbs. at 7d. per lb.	L.7,000,000	
Wages of 800,000 weavers, spinners, bleachers, &c. at L.22. 10s. a year each	18,000,000	
Wages of 100,000 engineers, machine-makers, smiths, masons, joiners, &c. at L.30 a year each	3,000,000	
Profits of the manufacturers, wages of superintendence, sums to purchase the materials of machinery, coals, &c.	6,000,000	
		L.34,000,000

The capital employed may be estimated as follows:

Capital employed in the purchase of raw material	4,000,000
Capital employed in payment of wages	10,000,000
Capital vested in spinning-mills, power and hand-looms, workshops, warehouses, stocks on hand, &c.	20,000,000
	L.34,000,000

Of 288,674,000 lbs. of cotton wool imported into the united kingdom in 1831, 219,333,000 lbs. were from the United States, 31,695,000 lbs. from Brazil, 25,805,000 from the East Indies, 7,714,000 lbs. from Egypt, 2,401,000 lbs. from the British West Indies, 334,000 lbs. from Colombia, 366,000 lbs. from Turkey and Continental Greece, 344,000 lbs. from Malta, &c. (*Parl. Paper, No.* 550, *Sess.* 1833.)

Burns' *Glance*, a tabular statement, annually published at Manchester, and admitted to be drawn up with great care, contains an account of the cotton spun in Great Britain in 1832, and how that spun in England was disposed of, with several other interesting particulars.

Statement of Cotton spun in England and Scotland in 1832, *and the Quantity of Yarn produced; showing also the Quantity spun in England, and how disposed of.*

	Number of Bags consumed.	Average Weight of Bags in lbs.	Total Weight in lbs.	Weekly Consumption of Bags.
American cotton	615,402	345	212,313,690	11,834·34
Brazil ditto	135,298	180	24,353,640	2,601·46
Egyptian ditto	45,864	220	10,090,080	882·00
West India ditto	6,454	300	1,936,200	124·06
East India ditto	55,416	330	18,287,280	1,065·36
Taken from inland stock	33,160	310	10,279,600	637·36
Total number of bags consumed	891,594		277,260,490	17,146·20
Allowed for loss in spinning, 1¾ oz. per lb.			30,325,366	lbs.
Total quantity of yarn spun in England and Scotland				246,935,124
Deduct yarn spun in Scotland				24,338,217
Total quantity of yarn spun in England				222,596,907
HOW DISPOSED OF.				
Exported in yarn during the year			71,662,850	
——— thread			1,041,273	
——— manufactured goods			61,251,380	
Estimated quantity of yarn sent to Scotland and Ireland			5,700,000	
Exported in mixed manufactures not stated in the above named articles, consumed in cotton banding, healds, candle and lampwick, wadding, and loss in manufacturing goods			12,000,000	
Balance left for home consumption and stock			70,941,404	222,596,907

This annual quantity of 222,596,907 lbs. gives a weekly supply of 4,280,709 lbs. Mr Burns estimates the quantity spun per spindle, per week, at 8½ oz. making the total number of spindles employed in England and Wales, in 1832, amount to 7,949,208. Those employed in Scotland during the same year are estimated, in the same way, at 881,020. Mr Burns further calculates the number of looms employed in England and Wales at 203,703. The consumption of flour in the manufacture is much greater than any one not pretty well acquainted with it would really suppose. The average quantity required for each loom is estimated at 4 lbs. per week; making the total annual consumption in England and Wales 42,301,584 lbs. or 215,824 barrels of 196 lbs. each.

Such being the vast extent and importance of the cotton manufacture, the probability of our preserving our ascendency in it becomes a very interesting topic of inquiry. But it is obvious that a great deal of conjecture must always insinuate itself into our reasonings with respect to the future state of any branch of manufacturing industry. They are all liable to be affected by so many contingent and unforeseen circumstances, that it is impossible to predicate, with any thing like certainty, what may be their condition a few years hence. But abstracting the effects of national struggles and commotions, which can neither be foreseen nor calculated, we do not think there is any thing in our state, or in that of the different commercial and manufacturing countries of the world, which should lead us to anticipate that the gloomy forebodings of those who contend that the cotton manufacture of England has reached its zenith, and that it must now begin to decline, will be realized. The natural capabilities we possess for carrying on the business of manufacturing are, all things considered, decidedly superior to those of any other people. But the superiority to which we have already arrived is perhaps the greatest advantage in our favour. Our master manufacturers, engineers, and artisans, are more intelligent, skilful, and enterprising, than those of any other country; and the extraordinary inventions they have already made, and their familiarity with all the principles and details of the business, will not only enable them to perfect the processes already in use, but can hardly fail to lead to the discovery of others. Our establishments for spinning, weaving, printing, bleaching, &c. are infinitely more complete and perfect than any that exist elsewhere; the division of labour in these is carried to an extent incomparably greater; the workmen are trained from infancy to industrious habits, and have attained that peculiar dexterity and sleight of hand in the performance of their separate tasks, which can only be acquired by long and unremitting application to the same employment. Why, then, having all these advantages upon our side, should we not keep the start which we have already gained? Every other people who attempt to set up manufactures must obviously labour under the greatest difficulties as compared with us. Their establishments cannot at first be sufficiently large to allow the division of employments to be carried to any considerable extent, at the same time that expertness in manipulation, and in the details of the various processes, can only be attained by slow degrees. It appears, therefore, reasonable to conclude that such new beginners, having to withstand the competition of those who have already arrived at a very high degree of perfection in the art, must be immediately driven out of every market equally accessible to both parties; and that nothing but the aid derived from restrictive regulations and prohibitions will be effectual to prevent the total destruction of their establishments in the countries where these are set up. (M'Culloch's *Commercial Dictionary*, article *Cotton Manufacture.*)

The seats of the cotton manufacture of England are, first, Manchester, which takes decidedly the lead of all other places; and, secondly, Preston, Bolton, Blackburn, and Wigan, all situated in Lancashire. After these come several other places, partly in Lancashire, in Cumberland, and the West Riding of Yorkshire. The introduction of cotton works into the last, the great seat of the woollen manufacture, is owing to the practicability of the same workmen turning, in case of need, from wool to cotton, and *vice versa.*

ardware. We have already noticed the surprising increase in the produce of our iron mines since 1780. This increase of the raw material, joined in some cases to the command of coal in the vicinity, and in all to a facility of conveyance of coal and iron by canals, has, in the last forty years, given a great extension to our hardware manufacture. In it we take the lead of foreigners as decidedly as in our cottons; and if the ratio of increase has not been altogether so rapid, it is owing, not to inferior ingenuity in the workmen, but to radical differences in the two manufactures. In no department has the subdivision of employment been carried to so great a length; in none are its effects in cheapening production so conspicuous. Birmingham and Sheffield are the two great work-shops for our hardware; the latter is confined to iron and steel; whilst, in the former, not only iron and steel, but copper and brass, constitute the materials of labour. Sheffield fabricates articles which are less for ornament than utility, and which possess, in general, a certain bulk, such as grates, spades, sickles, files, knives, fenders, fire-irons; whilst in Birmingham there is, in addition to articles of solidity, a surprising variety of toys, fancy goods, and petty manufactures; each trifling when considered separately, but the whole forming an aggregate of great value. The most insignificant of these, such as a brass cock or a button shank, passes through a number of hands; and each artisan performs only a single operation. He thus acquires an extraordinary dexterity in his limited department, and, in the course of a day, dispatches several hundred, perhaps even a thousand articles, through his particular stage; the result of all which is, that the price, when sold in quantities, is incredibly low. Another and very interesting feature in the situation of Birmingham, is the populousness of its neighbourhood. Yet in none of our large towns is living less expensive; an advantage owing partly to the abundance of coal, partly to the ready supply of milk and vegetables from the wide space occupied by the population.

The nail trade is carried on, not in the town of Birmingham, but in a part of the surrounding district: it is computed to employ 30,000 men, women, and children; for even this heavy article admits of a subdivision of employment, which lightens the labour, and enables the workman to avail himself of the aid of his family. Of the two towns, Sheffield is by much the more ancient; the command of coal and iron in the same neighbourhood having rendered it, so far back as the thirteenth or fourteenth century, a place for the fabrication of the homely articles used in these days by our ancestors. It is about a century since its razors, knives, and files began to take a more delicate shape. Birmingham, however, embraced a wider range, and advanced with much greater rapidity; but Sheffield also has its adjacent district inhabited by manufacturers, though to a much less extent than the vicinity of Birmingham. This district, called Hallamshire, extends six or seven miles to the west of Sheffield.

Hardware is made in several other places, such as Bilston, Wolverhampton, Dudley, and Walsall. Each of these towns is situated in Staffordshire, and, in point of manufacture, is small only in comparison with Birmingham or Sheffield. Articles apparently very trifling are manufactured to a surprising extent in different places, such as pins at Gloucester, needles at Red-ditch in Worcestershire, watch movements and main springs at Prescott in Lancashire. The total value of our articles of iron, steel, brass, and copper, including the manufacture from its earliest to its most finished stage, is necessarily fluctuating, but may be computed at L.16,000,000 annually; two thirds of which appear to be consumed amongst ourselves, whilst the other third is exported to two great markets, the Continent of Europe and the United States of America. A return during three years of peace, but of unequal mercantile prosperity, will suffice to show the average of annual export.

Quantity and Real Value of Metals and Hardware exported from Britain in 1831.

	Quantity.	Real Value.
1. Metals, as a RAW MATERIAL, or in the first stage of manufacture.		
Iron and steel, wrought and unwrought	Tons 124,312	L.1,123,372
Lead and shot (partly from Scotland)	... 6,777	96,333
Tin, unwrought	Cwts. 21,763	77,718
2. MANUFACTURES in a finished state.		
Hardware and cutlery	... 336,194	1,622,429
Brass and copper manufactures	... 181,951	803,124
Plate, plated ware, jewellery, and watches	... .	188,144
Tin and pewter wares, and tin plates	... .	230,143

The number of persons, young and old, employed in the hardware manufacture, is reckoned at between 300,000 and 400,000. In no branch of industry is the transition from war to peace more sensibly felt; government, the great customer for arms and artillery, withdraws entirely from the market; whilst the stagnation of commerce, the postponement of new buildings and new machinery, in short, the various evils inseparable from a sudden and general change, which have been so cruelly felt throughout Britain since the peace, all operate most materially against the sale of the heavier and more useful articles. Similar causes cast a damp over the purchase of ornamental and fancy goods; so that in no department of our population have the sufferings of the labouring classes or the augmentation of the poor's rate been greater. But there is happily a point beyond which depression cannot go; the reduced price of a commodity rendering it applicable to more extended uses, and adapting it to the means of humbler customers. Iron has not been found suitable as a substitute for stone in paving the streets of the metropolis; but, if its price continue low, it is likely to supplant timber for a variety of purposes, of which the public at large are not as yet aware. Reduction of price will lead also to a demand from the Continent for our hardware; the article in which of all others the French and Germans are most behind us. Their mines of iron are seldom adjacent to their mines of coal, and, with the exception of a few places, such as Liège in the Netherlands, and St Etienne near Lyons, the hardware workmen are not collected in such large associations as to admit of the necessary subdivision of labour. As improvement advances, and a taste for comfort becomes diffused, the inhabitants of the Continent will extend their purchases; they will see in the keys, the locks, and other neat and convenient articles of English fabric, a substitute for the bolts, the latches, and other coarse contrivances, with which they have hitherto been obliged to content themselves. In the United States, iron and coal are found, it is said (Mellish's *Travels in America*, chap. 67), in abundance, in a quarter (Pittsburgh in Pennsylvania) where land and provisions are certainly much cheaper than in Britain; but the scattered state of American population must, during several ages, oppose serious obstacles to the division of employment necessary in all the nicer branches of the hardware manufacture; particularly as the ease with which the Mississippi and Ohio are navigated by steam opens even the western states to the importation of British goods. Upon the whole, therefore, we look on our hardware manufactures, notwithstanding their present depression, as resting on a solid basis, because in them we combine several advantages;—the raw material, the command of cheap fuel, and the use of machinery, which, the more it is adopted, will bring a greater proportion of the work within the compass of women and boys, and thus lessen the proportion borne by wages in the cost of the finished article.

Linen manufacture.

Linen has never formed one of the staple manufactures of England, flax having been less cultivated amongst us than on the opposite shore of the Netherlands; a country which, in the fourteenth and fifteenth centuries, supplied the rest of Europe with the finest linens and woollens. When England subsequently advanced in manufacturing arts, the abundant supply of wool pointed out the most suitable branch; and we were contented to continue our imports of linen from the Netherlands, from France, and from Germany, or to favour the manufacture of the sister island in a department which did not excite our jealousy. In Ireland, the linen manufacture dates about two centuries ago, and is said to have owed much of its extension to the measures of the unfortunate Wentworth in the reign of Charles I. The annual consumption of linen in England a century ago was probably not far below that of her double population at present, owing to the very general substitution in our time of cotton articles. Then, as at present, the linen manufacture of England was established chiefly in Lancashire, in Cumberland, and in a county very remote from these, namely, Dorsetshire. In 1745 government, apprised of the extension of the manufacture of coarse linen in Silesia and other parts of Germany, and actuated by the fallacious notion of making a monopoly of all kinds of productive industry, granted a bounty of 1½d. per yard on the exportation of all British linen of a value from 6d. to 18d. per yard; in other words, a premium of 20 or 25 per cent. on the prime cost of all inferior qualities exported. So large a grant soon augmented the manufacture of osnaburgs and other coarse cloths, particularly in Scotland, although the ratio of increase was infinitely smaller than in the case of cotton, where there was no premium, but a rapid improvement of machinery. The demand for bounty, in the ten years ending in 1785, was about L.33,000 annually. More recently these impolitic issues were greatly increased; but at length the impolicy of forcing a manufacture in this way having become obvious to every one, the bounties, after being gradually reduced, ceased finally in 1830.

Ireland and Scotland, particularly Dundee, are both superior to England in the manufacture of linen. But some of the flax mills established at Hull are on a more extensive scale than any other in the empire. The reader will find under the head of LINEN, in this work, an account of the value of the manufacture in each division of the empire, of the amount of capital, and the number of hands employed in it, &c.

Silk man facture.

In the silk manufacture, as in linen, we have had to contend with a formidable opposition in other countries, particularly in France and Italy; and we have also had to import the whole of the raw material. It would therefore hardly have been attempted by our countrymen, but for the great profits expected from an article of general use amongst the higher classes. Its introduction amongst us goes back to the fifteenth century. About the beginning of the seventeenth it seems to have been carried to a considerable extent, owing certainly not to the luxury of the age, nor to any great proportion of affluent persons in the community, but to silk being almost the only article of apparel in which the vanity of dress could display itself. Towards the end of the reign of Charles II., about the year 1680, raw silk began to be imported in quantities from India; and the English manufacture received a substantial addition by the numbers and ingenuity of the Frenchmen who settled in this country after the revocation of the edict of Nantes in 1683. Various circumstances thus contributed to preserve and extend the manufacture, which continued rather upon the increase till the general substitution of cottons for silks about 1790. This gave a serious shock to the manufacture, from which it recovered only by slow degrees. Its situation had not indeed been at any time prosperous; and the continued complaints of the manufacturers occasioned within these few years a fundamental change in the policy under which it had previously been conducted.

From the first introduction of the manufacture into England down to 1825, foreign silks were either positively or virtually excluded. But the monopoly which was thus secured to the manufacturers produced, what all monopolies invariably do, an indifference to improvement. Instead of trusting to the ingenuity or to the superior skill which they might have called to their aid for preserving their ascendency in the market, the manufacturers depended upon custom-house regulations, and additional penalties on smuggling. In consequence, invention was quite at a stand. Such indeed was the influence of the system in this respect, that in 1826 the member for Coventry (Mr Edward Ellice) affirmed in his place in the House of Commons that the improved silk looms in use in various parts of the Continent enabled the workman to execute *five* times as much work as he could do here; whilst in every business not protected by a monopoly the result was precisely opposite. At length, after a great deal of discussion, it was resolved to adopt a more liberal system. In 1825 a bill was in consequence passed, allowing the importation of foreign silks on payment of an *ad valorem* duty of 30 per cent., accompanied, however, by the effectual reduction of the singularly oppressive duties which had previously been imposed on the imports of raw and thrown silk. This measure, though vehemently opposed at the time, has proved most successful. We are quite sure that we are within the mark when we affirm that the silk trade has made more progress since 1826, when the new system was introduced, than it did during the whole of the preceding century. The following is an account of the raw and thrown silk imported since 1820:—

Years.	Raw and Thrown Silk. lbs.	Years.	Raw and Thrown Silk. lbs.
1820	2,641,866	1827	3,610,727
1821	2,542,195	1828	4,765,241
1822	2,680,568	1829	3,805,933
1823	2,880,634	1830	4,318,181
1824	3,477,648	1831	4,621,874
1825	3,894,770	1832	4,224,897
1826	2,665,225		

This table shows conclusively that the manufacture has increased nearly 50 per cent. since the adoption of those sound and liberal measures which have been the theme of so much ignorant invective. It is of importance too to observe, that not only our imports of raw silk, but also our exports of manufactured silk goods, are rapidly increasing. The following table shows this.

Declared Value of all Sorts of British Manufactured Silk Goods exported each Year since 1820.

Years.	Declared Value.	Years.	Declared Value.
1820	L.371,775	1823	L.251,409
1821	374,473	1824	442,596
1822	381,703	1825	296,736
1826	L.168,801	1830	L.521,010
1827	236,344	1831	578,874
1828	250,870	1832	529,990
1829	267,931		

It is plain, therefore, that the manufacture is not increasing merely by reason of an increased demand in the home market, but because we are rapidly gaining on our rivals in the markets of foreign countries. This affords unquestionable evidence of the improvement as well as the extension of the manufacture. In 1832 our exports of wrought silks to France itself amounted to about L.75,000.

Leather manufacture.

Leather, however little it may figure as an article of export, is necessarily one of extensive home consumption in every civilized country, particularly in such a climate as ours, and where there are so many rich and sumptuous equipages. It is matter of regret that we should have so very few *data*, official or otherwise, on which to form an estimate of the export or import of hides in former ages. Such an estimate would possess interest, as indicating the extent of our pasturage and the number of our cattle in comparison with our population. Whatever may have been the case at a remote date, the custom-house returns, for many years past, show, by the annual imports, that the demand for leather has greatly exceeded the home supply of hides. For a long time this importation took place from the Continent of Europe, and from the least civilized quarters; from countries, such as Lithuania and Poland, where the quantity of hides furnished by the cattle materially exceeds that of the leather required by the inhabitants. But since the opening of the trade to South America, it has been found more advantageous to import hides from that continent, where the herds of wild cattle are so numerous as to meet the eye of the traveller in almost every point of the horizon.

On an average of the two years ending with 1832 there were imported 199,033 cwts. of untanned, and 24,334 cwts. of tanned hides. The quantity of leather annually made in England and Wales may be estimated at about 45,000,000 lbs. The largest tanneries are at Bermondsey in Southwark; but there are also very extensive establishments of the kind in the country, as in Cheshire, Lancashire, Westmoreland, Cumberland; and also in Lincolnshire. The late war, by its long continuance, and the magnitude of our army and navy, produced great orders from government for our leather manufacture. Shoes were and still are made wholesale in several towns of Staffordshire, Cheshire, and Northamptonshire; but those made in London, by the principal dealers, are, though expensive, by far the best.

Of the annual value of the leather manufactured into shoes, boots, harness, saddlery, &c. there are no means of forming a correct estimate; but we have merely to consider the population of England, and the unavoidable extent of their wants, to be satisfied that from ten to twelve millions sterling are rather below than above the mark. But whilst our home consumption is so considerable, our export is comparatively small, and does not exceed half a million sterling. To Ireland, the leather we ship is merely tanned; to other countries our exports are in a manufactured shape. The duty on leather was wholly abolished in 1830.

Glove trade.

Connected with our general manufacture of leather is the glove trade, a branch of no inconsiderable extent, being carried on in several of the midland and western counties, viz. at Woodstock, Worcester, Ludlow, Hereford, Yeovil in Somersetshire, &c. This branch of industry enjoyed for a lengthened period the protection of monopoly, which, however, was abolished in 1825. Many contradictory statements have been made as to the effects of this measure. We believe, however, that the depression so much complained of has not been produced by it, but by the substitution of cotton gloves for those of leather; and we have no doubt that, had it not been for the greater cheapness and improved quality of leather gloves, caused by the abolition of the monopoly, this substitution would have been carried much farther than it has been. The increased imports of the lamb and kid skins used in the manufacture show conclusively that it is not declining.

Brewery.

We come next to a branch of industry of a very different description, namely, the brewery. The amount of capital and labour invested in brewing establishments in England is very large, and particularly striking to those who have lived on the Continent, and have contrasted our situation with that of the wine countries of the south of Europe. It is only in Flanders and Germany that breweries are numerous; and, in the latter, from the limited capital, and the scattered state of their population, there are hardly any of those large establishments which exist in our metropolis. In London this important branch of business is chiefly in the hands of about a dozen great houses, who, conjunctly with the smaller establishments, brew at an average 1,800,000 barrels of porter.

The following account exhibits within a brief compass all the information that can be desired with respect to the consumption of malt and beer in England, and the duties thereon.

Account of the Quarters of Malt charged with Duty in England and Wales, with the Amount and Rate of such Duty; of the Malt used by Brewers and Victuallers in the same; of the Number of Barrels of each sort of Beer, and the Duties thereon; in each year from the 5th January 1821 *to the 5th January* 1833.

The duty on beer having ceased on the 10th of October 1830, there are no subsequent accounts of the quantities brewed. There can be no doubt, however, from the increased quantity of malt, that the production of beer has been materially increased.

Spirituous liquors form one of the branches of manufacture in which England is dependent on her neighbours, as she imports an annual supply of corn spirit from Scotland and Ireland, rum from the West Indies, and brandy from France. It has been generally supposed that the consumption of gin has increased materially in England since 1825, when the duties were reduced. We are, however, inclined to doubt whether such be really the case, and are disposed to believe that the effect is more apparent than real; in fact, that it has resulted rather from a diminution of smuggling than from a positive increase of consumption. That such has been the case in Scotland and Ireland is beyond all question; and there seems no reason to conclude that it is otherwise in England. We subjoin a statement of the quantity of the different sorts of spirits entered for home consumption in England in 1832, and of the duties thereon. The consumption of British spirits has declined about 500,000 gallons during the last three years. The annual average consumption of brandy is about 1,200,000 gallons. Its increase in 1832 is to be ascribed to the notion then prevalent, but since exploded, that brandy potations formed one of the best antidotes to cholera.

Lesser m nufactur glass, hat pottery.

To the remaining manufactures our limits allow of little space, though several of them would be accounted of great importance in any other country than England. The extent to which such articles as soap and paper are made among us is amply shown by the excise returns; but the list of our exports is of more consequence to the political economist, not from the vulgar notion that it is by export only that national profit is realized, but as indicative of those commodities for which we possess, in our soil, our climate, or our colonial possessions, advantages that give us a superiority over our neighbours. Thus, in the case of glass, the abundance and cheapness of our coal outweigh the disadvantages arising from the duty, and enable us to make an annual export of between L.400,000 and L.500,000. In the manufacture of hats, likewise, our command of wool for the coarser kind, and of furs from our North American colonies for beaver hats, enables us to ship to an extent of nearly L.200,000 real value a year. In earthenware we have the advantage of clay, of fuel, and of ready communication by canals. These, joined to the taste and ingenuity of individuals engaged in the manufacture, carried it, in the course of the eighteenth century, to an extent which has rendered it a national object; a tract of seven or eight miles in Staffordshire, called the Pottery District, being almost entirely appropriated to it. The population of this tract is about 60,000. The great outlet is Liverpool, and the shipments take place partly to the United States, partly to the continent of Europe. Our exports, comprising porcelain, average from L.400,000 to L.500,000 real value.

The stocking manufacture is carried on chiefly in the counties of Nottingham, Derby, and Leicester. It formerly employed vast numbers of women in knitting; but in this, as in most other branches, machinery has greatly superseded manual labour. Lace is made in vast quantities in the midland counties; and here also machinery has of late years been extensively applied. And so extraordinary has been the progress of invention in this department, that British lace at present commands a ready sale in all foreign markets, and is largely smuggled even into France.

We shall give, in a subsequent section, an account of the number of persons supposed to be employed in trade and manufacture, according to the returns obtained under the population act for 1821.

VIII.—*Commerce and Shipping.*

Much of what relates to the commerce of England has been already treated of under the preceding section, and the colonial part of our trade shall be noticed in the next. At present we are to exhibit a brief sketch of our commercial intercourse with Ireland and the continents of Europe and America.

With Ireland the intercourse of England is very great, that country sending us grain, salted and fresh provisions, live cattle, butter, &c. to the amount of six or seven millions annually, and taking largely in return our manufactures, particularly cotton, woollen, and hardware.

North of Europe.—From Russia our chief imports are tallow, hemp, flax, corn, linen, timber, pitch, &c.; from the Swedish dominions, iron and timber; from Poland, wheat, timber, and potash; from Prussia, wheat, timber, and flax. All these countries take our cottons, hardware, and colonial produce.

Central part of Europe.—From Holland our imports are not foreign merchandise, as in the seventeenth century, when the Dutch were the carriers of Europe, but agricultural produce, as oats, wheat, seeds, hemp, cheese, butter; also gin; the whole to a large amount; in return for which the Dutch take our hardware, cottons, and woollens. From France our imports have long been burdened with heavy duties, but still they are large and increasing; consisting chiefly of wine and brandy, and also of silk, lace, and gloves. With Germany our chief intercourse is through the medium of Holland and Hamburg. Our exports are large, particularly in cottons, hardware, and colonial produce. Our imports are also very various and large, consisting of wool, corn, flax, timber, linen, and wine, from the vicinity of the Rhine.

South of Europe.—Here we enter on countries of much less industry. From Portugal we take wine in very large, and fruit in smaller quantities, in return for our cottons, our woollens, and our hardware. From Spain we receive wool, wine, brandy, oil, fruits, barilla, &c. Italy, without any commercial treaty, takes annually a large quantity of our manufactures, and gives in return silk, oil, and fruit. With the Levant our traffic is similar; consisting of an export of manufactures, particularly printed cottons and hardware, and of an import of silk, fruit, and drugs.

The *United States* are, notwithstanding their tariff, our best customers, receiving from us manufactures of almost every kind to a great amount, and sending us in return vast quantities of cotton, tobacco, rice, and flour; but the merchandise received from them being far inferior to the value of our exports, the difference is paid by remittances in money from the Continent of Europe, arising from American merchandise sold there. With South America a wide field of commercial intercourse has been opened; at present, however, the chief articles received from that vast region are bullion, hides, skins, indigo, and cochineal. The trade is, and will long be, subject to the various disadvantages of a newly-settled country, bare of capital, deficient in industry, and possessing but a small number of consumers of European commodities in proportion to its extent and fertility.

From *Asia* we import tea, indigo, cotton, coffee, sugar, piece goods, ivory, drugs, &c. Our principal article of export is cotton goods, for which, how singular soever it may appear, India has, since the opening of the trade in 1814, become one of our very best markets. Besides cotton stuffs and yarn, we send to Asia woollen goods, copper, and a great variety of other articles.

From *Africa* we import drugs, ivory, teak wood, hides, &c. Our exports are but inconsiderable, consisting principally of cotton and linen manufactures. The hopes so frequently entertained, of opening an advantageous trade with the interior of Africa, have hitherto been altogether disappointed, and we do not suppose that they are destined to be more successful in future.

Foreign trade.

The following accounts refer to the trade of Great Britain. It appears, however, from the statement of the customs duties collected in the different parts of the empire in 1831, and which are given in a subsequent part of this article, that the foreign trade of Scotland does not, on an average, exceed an eleventh or twelfth part of that of England. The trade of Ireland is about as great as that of Scotland.

I.—*Official and Declared*[1] *Value of Exports of British and Irish Produce and Manufacture, and Official Value of Exports of Foreign and Colonial Merchandise from Great Britain, and Official Value of Imports into the same, for the following Years.*—(Parl. Paper, No. 243, Sess. 1830; and Finance Accounts.)

---

[1] For an explanation of the difference between official and real value, see EXCHANGE.

[2] Records destroyed by fire.—From the year ending the 5th of January 1815 inclusive, British produce and manufactures have been included in the returns of Irish produce, &c. from Ireland, and consequently omitted in the column headed Exports, Foreign, Colonial, and British, under which they had been previously returned.

II.—*Account of the Official Value of the Imports into the United Kingdom, and of the Exports of British and Irish Produce and Manufactures, and of Foreign and Colonial Merchandise, in the year* 1831, *specifying the Imports from and Exports to each Country.*—(Parl. Paper, No. 336, Sess. 1833.)

Decline in he real value of the xports.

The increase in the official, and the decline in the real or declared value of the exports, since 1815, has given rise to a great deal of irrelevant discussion. It has been looked upon as a proof that our commerce is daily becoming less prosperous, whereas, in point of fact, a precisely opposite conclusion should be drawn from it. We have already stated, that the rates according to which the official values of the exports are determined, were fixed as far back as 1696; so that they have long ceased to be of importance as affording any criterion of the actual value, their only use being to show the fluctuations in the *quantities* exported. To remedy this defect, a plan was formed during the early part of Mr Pitt's administration, for keeping an account of the *real* value of the exports, as ascertained by the declarations of the exporters. Those who contend that our trade is getting into a bad condition, argue that the great increase in the official value of the exports since 1815 shows that the *quantity* of the articles exported has been proportionally augmented, whilst the fall in their real value shows that we are selling this larger quantity for a smaller price, a result which, they affirm, is most injurious. But the circumstance of a manufacturer or a merchant selling a large or a small quantity of produce at the same price, affords no criterion by which to judge as to the advantage or disadvantage of the sale; for if, in consequence of improvements in the arts or otherwise, a particular article may now be produced for half the expense that its production cost ten or twenty years ago, it is obvious that double the quantity of it may be afforded at the same price without injury to the producers. Now this is the case with some of the most important articles which are exported from England. Cottons and cotton-twist form a full half or more of our entire exports; and since 1814 there has been an extraordinary fall in the price of these articles, occasioned partly by cotton wool having fallen from about 1s. 6d. per lb. to about 7d. per lb., but more by improvements in the manufacture. To such an extent have these causes operated, that yarn No. 40, which in 1812 cost 2s. 6d., in 1830 cost 1s. 2½d.; in 1812 No. 60 cost 3s. 6d., in 1830 it cost 1s. 10½d.; in 1812 No. 80 cost 4s. 4d., in 1830 it cost 2s. 6¾d., and so on; and in the weaving department the reduction has been similar. Hence, whilst the official value of the exports of cotton goods and twist has increased from about L.18,000,000 in 1814, to about L.37,000,000 in 1830, their declared value has sunk from about L.20,000,000 at the former period to about L.16,000,000 at the latter. Surely, however, this is, if any thing can be, a proof of increasing prosperity; it shows that we can now export and sell with a profit (for unless such were the case, does any one imagine the exportation would continue?) nearly double the quantity of cotton goods and yarn which we exported in 1814 for about the same price. In as far, therefore, as an abundant and cheap supply of cottons may be supposed to increase the comforts of society, it is plain that they must be about double, not in this country only, but in all those countries to which we export. (M'Culloch's *Commercial Dictionary*, art. *Cotton.*)

Shipping.

The subjoined tables give a complete view of the shipping belonging to the different ports of the British empire, and of the navigation with foreign countries, in 1829 and 1830, since which time there has been no sensible variation.

I.—*Number of Ships and Vessels belonging to the different Ports or Places of the British Empire in* 1829, *stated in succession, agreeably to the Amount of Tonnage belonging to each.*

IX.—*Establishments for Religion and Education.*

Rank of the clergy.

The church of England has two archbishops and twenty-four bishops, all peers of the realm, and all indebted for their appointment to the crown. The bishop of the Isle of Man, formerly appointed by the Duke of Atholl, is now also appointed by the crown, but has no seat in the House of Lords. The province of York comprises four bishoprics, viz. Durham, Carlisle, Chester, and the Isle of Man; all the rest, to the number of twenty-one, are in the province of Canterbury. The clerical dignitary next to the bishop is the archdeacon, whose duty, though very different in different dioceses, may be termed that of a representative of the bishop in several of his less important functions. The number of archdeacons in England is about sixty. The name of Dean (*Decanus*) was probably derived from his originally superintending ten canons or prebendaries. Each bishop has a chapter or council appointed to assist him, and each chapter has a dean as its president; but there are in the church of England many deaneries of other descriptions. Rector is, in general, the title of a clergyman holding a living, of which the tithes are entire; vicar is understood of a living where the great tithes have passed into secular hands. The very general name of curate signifies sometimes (as *curé* in France) a clergyman in possession of a living, but more frequently one exercising the spiritual office in a parish under the rector or vicar. The latter are temporary curates, their appointment being a matter of arrangement with the rector or vicar; the former, being more permanent, are called perpetual curates, and are appointed by the impropriator of the tithe in a parish which has neither rector nor vicar. The name of priest is, in general, confined to the clergy of the church of Rome; in the church of England the corresponding term is a clerk in orders. A parson (*persona ecclesiæ*) denotes a clergyman in possession of a parochial church. Deacon is, in England, not a layman, as in Calvinist countries, but a clergyman of limited qualifications, entitled to preach, baptize, marry, and bury, but not to give the sacrament. Readers are not regular clergymen, but laymen of good character, licensed by the bishop to read prayers in churches or chapels where there is no clergyman. (See Adolphus *on the British Empire*, vol. i.)

A clerical education in England is of much less length than in Calvinist countries; in Scotland, Holland, Switzerland, or the north of Germany, after going through a course of classics and philosophy, a second course is required for theology solely; but in England the former is sufficient. The degree of bachelor of arts requires an examination and a university residence of three or four years; but to qualify for the acceptance of a curacy, a certificate of attending a single course of lectures in divinity is all that is necessary.

Livings.

The number of church livings in England and Wales is very great, being fully 10,500. From this multiplicity of benefices, and from the general smallness of the incomes, have arisen two great irregularities, pluralities and non-residence, both forbidden by the ancient statutes of the church, but both long sanctioned by usage. Many clergymen hold livings without doing duty at any of them; others do duty in one or in two which are adjacent to each other, and have a curate for the more distant; whilst curates frequently do duty at two and sometimes at three distinct places of worship. To prevent, or at least to lessen, the abuse of non-residence, an act of parliament was passed in 1813, directing that every non-resident incumbent should nominate a curate at a salary of not less than L.80 a year, unless the entire living should be less. The effect of this act was to reduce the number of non-resident clergymen by 800 fully; they had previously been about 4700; but in 1815 the official return to parliament of the incumbents in England and Wales was as follows:

Non-resident from the following causes:

Sinecures	52
Vacancies	164
Sequestrations	40
Recent Institutions	87
Dilapidated Churches	32
Held by Bishops	22
Law-suits, absence on the Continent, &c.	122
Livings from which no report	279
	798
Incumbents non-resident from other causes	3,856
Incumbents resident	5,847
	10,501

Tithes.

The rental of England and Wales was, by a late return, discriminated as follows in regard to tithes:

Tithe-free *in toto*	L.7,904,379
Tithe-free in part	856,185
Free on payment of a *modus*	498,823
Subject to tithe	20,217,467
Total	L.29,476,854

A part, and by no means an inconsiderable one, of the tithes of England, is held by laymen; but as the church has other sources of income, its total revenue is computed at nearly L.3,000,000; but the absorption of large sums by several of the prelates, as the Bishops of Durham, Winchester, and London, and the accumulation of the best livings amongst a few individuals of influence, reduce the annual average income of the curates, or most numerous class, to little more than L.100 a year.

Tithes necessarily fluctuate with the state of agriculture, and, during the distress of 1815, the deficiency in this respect became alarming. It was then that the clergy felt what they should have felt long before, that tithe was an unsuitable and impolitic source of revenue. Application was made to parliament, and the subject was for some time under serious discussion; but the rise of corn in 1816 and 1817 prevented any other measure than an act founded on a committee report of 18th June 1816, authorizing the possessors of tithes, laymen as well as clergymen, to grant leases of them for a term not exceeding fourteen years. The dissatisfaction with tithes has now, however, become so very general that we have no doubt a commutation of some sort or other must shortly take place.

A return to parliament, in June 1817, has specified the incomes of those benefices where there is no parsonage-house, or at least none that forms a suitable residence.

	Livings.
From L.10 to L.100	615
L.100 to L.150	442
L.150 and upwards	793
	1850

Churche

A prior and more comprehensive return had stated the number of churches and chapels for the established faith at 2533; and as these were inadequate (the members of the established church being about five millions, or half the population of England and Wales), an act was passed in 1818, and even pecuniary aid given by government, for the erection of a number of additional churches. The previous attempts to raise the requisite funds by the issue of briefs and voluntary subscriptions had exhibited a miserable specimen of misapplied labour, the expenses of atistics.

the collection, and of the patent and stamps, absorbing more than half the money received from the subscribing parties.[1]

erical
rms.

A prebend is a provision in land or money given to a church *in præbendum*, that is, for the support of a clergyman whose title may be either prebendary or canon. Advowson (*advocatio*) is the right of presentation to a living, and was first vested in those laymen who were founders of or benefactors to livings. A living is held *in commendam* when, to prevent its becoming void, it is committed (*commendatur*) until it can be conveniently provided with a pastor. The *modus* (*modus decimandi*) is a composition for tithes; it may be either perpetual or during the lives of the contracting parties. The lay impropriators of tithe, so frequent in England, date from the dissolution of the monasteries in the reign of Henry VIII.; patrons were then allowed to retain the tithes and glebe in their own hands, without appointing a clergyman; in cases of such appointment, the clergyman was called *vicarius* or representative of the patron.

ssenters.

The dissenters in England are, first, the Presbyterians, who nearly coincide with the church of England as to doctrine, but differ in church-government, allowing no hierarchy in individuals; next the Independents, who go further, and disclaim hierarchy in synods and other collective assemblies; thirdly, the well-known sect of Quakers, who date from the middle of the seventeenth century; and, lastly, the more numerous Methodists, who date from 1729. Of the Anabaptists, the chief characteristic is their not receiving baptism till they become adults. The Catholics in England are not numerous, but comprise a large proportion of wealthy families.

ducation.

In regard to the mode of education in England, there is much both to commend and to censure. Scotland has for a century past been in possession of a larger proportion of parish schools; but the utility of these is much lessened by an established routine of teaching Latin to almost all youths, whatever be their intended line of life. In England this absurdity is less prevalent, because most of the schools are private undertakings, the managers of which are necessarily guided by considerations of utility. The youth destined for a life of business are thus saved a serious waste of time; their education, if imperfect, is not supererogatory; but, on examining the higher seminaries of England, we find much ground for disappointment, and many marks of a blind adherence to ancient usage. Two universities are evidently inadequate for the education of the nobility, the gentry, and the clergy of so populous a country. Their course of study, also, is quite unsuitable to the future occupations of many of the students. They were originally designed for the education of churchmen; and, to this day, Latin, Greek, and mathematics form the chief objects of instruction. Under a government which has so long borne the representative form, there are no classes for the study of political science and legislation. In the country of Locke there are no classes devoted to the study of the philosophy of the mind. In short, there are scarcely any of those public lectures which, in the rest of Europe, constitute the grand characteristic of a university, and distinguish it from schools; all, or nearly all, is done by private tuition. Again, in point of constitution, whilst in other countries a university forms, in general, one large association, in England each college is a distinct body, having its head, its fellows, and its students, who, as far as education is concerned, have very little connection with the rest of the university. In one point, however, these venerable seminaries redeem their faults, and assert the dignity of their character; we mean in their public examinations. These, since the early part of the present century, have been put on an admirable footing, both at Oxford and Cambridge; distinguishing the relative degrees of proficiency with great accuracy, and converting into a full and impartial trial that which in other universities is almost always a mere matter of form.

Statistics.

Education of the poor.

No country rivals England in the magnificence of her academical buildings. Whilst in France, Germany, or Holland, an university possesses only a single pile of building, Oxford and Cambridge can boast for every college a large, commodious, and generally an elegant structure. The endowments appropriated to them are very various, both in their origin and destination, but these arise chiefly from land, and, having increased with the rise of rents, are in many cases very ample. The destination of these funds is regulated by the bequest of the donors and the established usage of the colleges; part going to the students under the name of exhibitions or scholarships; part to the head and fellows; and a further part consisting in livings, which devolve in succession on the fellows, and lead to their removal from the university. A hall is an inferior college; an academical establishment not incorporated or endowed, but possessed of exhibitions or other provisions for students. Oxford has nineteen colleges and five halls; Cambridge has twelve colleges and four halls.

Within these few years two institutions of a novel kind, the London University and King's College, have been founded in the metropolis, in the view of obviating the defects complained of at Oxford and Cambridge, and of cheapening and diffusing the advantages of an academical education; but their success has not corresponded with the expectations of their projectors. Their constitution appears ill fitted to attain the objects in view; and it is very questionable, unless they be materially modified, whether they will ever be of any material service. The education which they afford is neither very good nor very cheap.

Boys in England are taught the classics, either in the lesser schools established at every town of consequence throughout the kingdom, or at the great public schools. Of the latter, the principal are Eton, Westminster, Winchester, and Harrow; also the Charter-house, St Paul's, and Merchant Tailors' School. These seminaries, at present so expensive, and attended by youths of the first family, had their origin in a fund or provision set apart for scholars of humbler birth. This has served as the basis of a stately superstructure, each school having attracted, by the advantage of situation or the repute of the teachers, a much greater number of pupils in independent circumstances. But in each a proportion of the scholars are still on the foundation. At Eton there are seventy thus provided for; and the same number at Winchester.[2] This subject will be resumed, and treated in detail, under the articles NATIONAL EDUCATION, SCHOOLS, and UNIVERSITIES.

X.—*Establishments for purposes of Charity.—Poor-Rates.*

The public charities of England are very numerous; the bequests of benevolent founders in this country exceeding those of the zealous Catholics of France or Spain, as well as those of the once affluent Protestants of Holland. Our limits admit of the notice of only a few of the foundations in the metropolis and its neighbourhood.

---

[1] See *Return of Briefs delivered to Parliament*, 19th May 1819.

[2] *Reports of the Education Committee*, 1817 and 1818.

Amongst the principal *Hospitals* are,

- Bethlem Hospital.
- St Luke's, Old Street.
- St Bartholomew's, West Smithfield.
- Guy's, in Southwark.
- The Lock Hospital, Hyde-Park-Corner.
- The London Hospital, Whitechapel Road.
- The Magdalen Hospital, St George's Road.
- The Middlesex Hospital, Berner's Street.
- The Foundling Hospital.

Amongst the *Dispensaries* and medical charities are,

- The General Dispensary, Aldersgate Street.
- City Dispensary in the Poultry.
- Finsbury Dispensary.
- Various Vaccine Dispensaries.
- The Fever Hospital, instituted in 1801.

A *College*, in the sense of a charity, is an alms-house on an enlarged scale, under the direction of a master and other incorporate officers. There are only three in the neighbourhood of London, namely, Bromley, Morden, and Dulwich Colleges.

Alms Houses.—These are very numerous, viz. the Haberdashers', Mercers', Skinners', East India Company's, &c.

School Charities.—These institutions are also very numerous. Amongst the most remarkable are,

- Christ's Hospital, or the Blue Coat School.
- Marine Society.
- School for the Indigent Blind.
- Deaf and Dumb Asylum.
- Debtors' Children.
- Ladies' Charity School.
- Masonic Charity.
- Raines' Charities.

Miscellaneous Charities.—Under this head are comprehended several extensive and well-known associations.

- The African Institution.
- The British and Foreign Bible Society.
- Society for Bettering the Condition of the Poor.
- Society for Promoting Christian Knowledge.
- The Missionary Society.
- The Literary Fund.

A compulsory provision for the support of the poor has existed in England for a lengthened period. Its introduction dates from the reign of Henry VIII., and it was perfected in that of Elizabeth; the famous statute of the 43d Eliz. cap. 2, having embodied all the principles, with many of the regulations, still to be found in the system. The law has, however, been repeatedly modified, and very great alterations have taken place in its administration. These changes will be fully detailed in our article on the POOR-LAWS; and in it also the reader will find an examination of the important and difficult question as to the policy of a compulsory provision for the support of the unemployed poor. Here we have only to state what has been the amount of the rates levied on account of the poor, from what sources they have been derived, and how they have been distributed.

Account of Monies levied for Poor's Rates and County Rates in England and Wales; of the Payments thereout for other purposes than the Relief of the Poor, at all the several periods for which Returns have been required by Parliament; also the Average Price of Wheat at every such period, and the Amount of Population.

Years.	Total Sum levied for Poor's Rates and County Rates.	Payments thereout for other purposes than the Relief of the Poor.	Expended in Law Removals and similar Incidents.	Expended for the Relief of the Poor.	Total Expenditure.	Average Price of Wheat per Quarter.		Population.
						By the Winchester Bushel of Eight Galls.	By the Imperial Bushel of Eight Gallons.

yment wages t of or-rates.

It is obvious, from the preceding tables, that, allowing for the increase of population, the increase of the rates has not been nearly so great as is commonly supposed. In point of fact, too, more than half the rates really form part of the wages of labour. The pernicious practice of ekeing out wages by means of contributions from the rates began in 1795; and as it forms at this moment one of the principal evils in the state of the English poor, we may be excused, perhaps, for subjoining the following statements illustrative of its tendency.

"The price of corn, which had, upon an average of the three preceding years, averaged 54s., rose in 1795 to 74s. As wages continued stationary at their former elevation, the distress of the poor was very great; and many able-bodied labourers, who had rarely before applied for parish assistance, became claimants for relief. But instead of meeting this emergency as it ought to have been met, by temporary expedients, and by grants of relief proportioned to the exigency of every given case, one uniform system was adopted. The magistrates of Berks, and some other southern counties, issued tables, showing the wages which, as they affirmed, every labouring man ought to receive, according to the variations in the number of his family, and the price of bread; and they accompanied these tables with an order, directing the parish officers to make up the deficit to the labourer, in the event of the wages paid him by his employers falling short of the tabular allowance. An act was at the same time passed to allow the justices to administer relief out of the workhouse, and also to relieve such poor persons as had property of their own. As might have been expected, this system did not cease with the temporary circumstances which gave it birth, but has ever since been acted upon. It is now almost universally established in the southern half of England, and has been productive of an extent of mischief that could hardly have been conceived possible.

"It is needless to dwell on the folly of attempting to make the wages of labour vary directly and immediately with every change in the price of bread. Every one must see, that if this system were *bona fide* acted upon, if the poor were always supplied with the power of purchasing an equal quantity of corn, whether it happened to be abundant and cheap, or scarce and dear, they could have no motive to lessen their consumption in seasons when the supply is deficient, so that the whole pressure of the scarcity would, in such cases, be removed from them and thrown entirely upon the other, and chiefly the middle classes. But, not to insist on this point, let us look at the practical operation of this system as it affects the labourer and his employers. The allowance scales now issued from time to time by the magistrates are usually framed on the principle that every labourer should have a gallon loaf of standard wheaten bread weekly for every member of his family and one over; that is, four loaves for three persons, five for four, six for five, and so on. Suppose, now, that the gallon loaf costs 1s. 6d., and that the average rate of wages in any particular district is 8s. a week, A, an industrious unmarried labourer, will get 8s.; but B has a wife and four children, hence he claims seven gallon loaves, or 10s. 6d. a week; and as wages are only 8s., he gets 2s. 6d. a week from the parish. C, again, has a wife and six children; he consequently requires nine gallon loaves, or 13s. 6d. a week, and gets of course a pension, over and above his wages, of 5s. 6d. D is so idle and disorderly that no one will employ him, but he has a wife and five children, and is in consequence entitled to eight gallon loaves for their support, so that he must have a pension of 12s. a week to support him in his dissolute mode of life.

"It is clear that this system, by making the parish allowance to labourers increase with every increase in the number of their children, acts as a bounty on marriage, and that, by increasing the supply of labourers beyond the demand, it necessarily depresses the rate of wages. And it is further clear, that by giving the same allowance to the idle and disorderly as to the industrious and well-behaved workman, it operates as a premium on idleness and profligacy, and takes away some of the most powerful motives to industry and good conduct. These, however, are not the only effects of this system. Under its operation a labourer dares not venture to earn beyond a certain amount; for if he did, his allowance from the parish would either be withheld altogether, or proportionally reduced. In consequence, working by the piece is now comparatively unknown in the southern counties of England; and the whole labouring population are reduced to the condition of paupers, deprived of the means and almost of the desire to emerge from the state of helotism in which they are sunk.

"It must be obvious to every one, that if we would avert the plague of universal poverty from the land, a vigorous effort must be made to counteract this system; and we have experience to teach us how this may be done. All, in fact, that is necessary, is to revert to the regulations established previously to 1795, to abolish every vestige of the allowance system, and to enact that henceforth no able-bodied labourer shall have a legal claim for relief, unless he consent to accept it in a workhouse. This condition would go far to prevent relief from being claimed by any except the really necessitous; for there is nothing of which the idle and disorderly are so much afraid, as of the strict discipline, scanty fare, and hard labour that ought to be enforced in every workhouse. It is not, however, meant to recommend that relief should in all cases be refused except to the inmates of such establishments. In the great majority of instances, that temporary assistance which the able-bodied poor only require may be more advantageously afforded at their own houses. But to prevent its being abused, it is indispensable that authority to refuse it, except under condition of residence in a workhouse, and of unconditional submission to all its regulations, should be vested in the administrators of the law. The maimed and impotent poor may, in all cases, be more cheaply and better provided for in their own houses than in workhouses.

"Were the change now proposed effected, most of the inconveniences attached to the poor-laws would be removed, and their salutary and sustaining influence would alone remain." (M'Culloch's *Principles of Political Economy*, 2d edit. pp. 418–421.)

XI.—*Establishments for the purposes of War and Defence.*

These consist, of course, principally of the army and navy. But as detailed accounts, derived from the very best sources, are given, under the articles Army and Navy in this work, of all the most important particulars relating to the history and present state of each of these grand departments of the public force, it would be quite superfluous to enter into any details with respect to them in this place. The subjoined accounts of revenue and expenditure during the three years ended with 1831, contain statements of the number of troops and seamen, and of the expense incurred on account of each branch of the service, in each of these years. They seem, therefore, to include every thing to which it is necessary to direct the reader's attention in this place.

Exclusively of the army and navy, great numbers of individuals in all parts of the country are enrolled as special constables, who may be called upon by the magistrates and other civil authorities to assist in suppressing disorders, and in preserving the public peace. In London and in other great towns strong bodies of police are also employed, constituting, as it were, a half military and half civil force.

[illegible] *Revenue and Expenditure.*

The various taxes, the produce of which forms the public revenue of the kingdom, will be described in the article Taxation in this work, where also their real incidence and practical operation will be pointed out. The subjoined tables give an account of the income and expenditure of the empire during each of the three years ending with 1831.

Account of the Public Income of the United Kingdom during each of the three years ending with the 5th of January 1832, specifying the different Taxes, and the produce of each.

XIII.—*National Debt.*

The national debt consists, as every one knows, of sums borrowed to make up deficiencies of revenue. It originated during the wars carried on by William III. against France. Its contraction was then not a matter of choice, but of necessity; for, owing to the numerous adherents the exiled family of Stuart had in the country, it would have been impossible to have imposed such an amount of taxes as would have sufficed to defray the expenses of the war, without inflaming the popular discontent to such a degree as would most probably have been subversive of the new government. At first it was usual to fund the amount of stock equal to the sums borrowed; but since the reign of George II. a different practice has obtained; and it has been judged advisable to fund generally in a stock bearing a low rate of interest, by proportionally increasing its amount. Thus suppose interest were five per cent. and that government wished to borrow in three per cent. stock; in such a case they would give L.166⅔ of stock for every L.100 money paid into the exchequer. By affording, in consequence of the increase of the stock, greater scope for speculation, this practice is supposed to have enabled government to borrow on rather lower terms at the time; but, by disabling them from reducing the interest on such loans at the close of a war, when the market rate of interest uniformly falls, it has proved most signally injurious. It is not going too far to say that this blunder costs the public at this moment L.7,000,000 a year.

	Principal.	Interest.
Debt at the accession of Queen Anne in 1702	L.16,394,702	L.1,310,942
Debt at the accession of George I. in 1714	54,145,363	3,351,358
Debt at the accession of George II. in 1727	52,092,238	2,217,551
Debt in 1763	138,865,430	4,852,051
Debt at the commencement of the American war in 1775	128,583,635	4,471,571
Debt at the conclusion of the American war in 1784	249,851,628	9,451,772
Debt at the commencement of the French war in 1793	239,350,148	9,208,495
Debt 5th January 1817, when the English and Irish exchequers were consolidated	848,282,477	33,854,466

Since 1817 a deduction has been made of about sixty-four millions from the principal of the debt, and about 5⅓ millions from the interest on its account. This diminution has been principally effected by taking advantage of the fall in the rate of interest since the peace, and offering to pay off the holders of the different stocks unless they consented to accept of a reduced payment; and had it not been for the highly objectionable practice already adverted to, of funding large capitals at a low rate of interest, the saving in this way would have been incomparably larger. We subjoin an account of the funded and unfunded debt of Great Britain and Ireland as at 5th January 1833.

nking
nd.

A sinking fund for the extinction of the public debt was established by Sir Robert Walpole as early as 1716; but it was virtually subverted in 1733. It was again instituted by Mr Pitt in 1786; and, singular as it may now appear, it was for a lengthened period supposed, that by means of the *legerdemain* operation of compound interest, the public debt might be reduced by borrowing money to pay it off. Dr Hamilton of Aberdeen has the merit of having dissipated this extraordinary delusion, the grossest, certainly, by which any civilized nation ever suffered itself to be imposed upon. He showed that the excess of revenue over expenditure is the only real sinking fund, —the only means by which any portion of the public debt had ever been, or ever could be, paid off; and that all sinking funds operating at compound interest, or otherwise, excepting in as far as they happened to be founded on this principle, were mere quackery and delusion. In fact, upon examining into the matter, it was found that the public debt would have been decidedly less had the sinking fund never been heard of. After such an exposition, the existence of the sinking fund was impossible; and having undergone various modifications, it was finally abolished by the 10th Geo. IV. cap. 27, which enacts, that the sum thenceforth annually applicable to the reduction of the public debt shall consist of the *actual surplus revenue beyond the expenditure.* In 1832 this surplus amounted to L.614,758. 18s. 8d.

XIV.—*Population.*

The population of England and Wales at periods antecedent to 1801, can only be determined by computations founded on the returns obtained under poll and hearth taxes, and on the registers of births and deaths. Unfortunately, however, none of these affords data from which the amount of population can be accurately deduced. During the latter part of last century the uncertainty in which this subject was involved afforded materials for a keen controversy, which was carried on by Dr Price on the one hand, and by Mr Howlett, vicar of Dunmow in Essex, and Mr Hales, on the other. The former contended that population had been declining in England from the Revolution downwards, and that it did not in 1777 exceed 4,763,000. Mr Howlett, however, showed conclusively that no reliance could be placed on either Dr Price's facts or arguments; and that there could be no reasonable doubt that the population had materially increased in the interval between 1700 and 1780. The returns obtained under the population acts put an end to this controversy, and proved the general accuracy of Mr Howlett's conclusions. The population, as deduced from them, after allowing for their defects and inaccuracies, is as follows:—

Years.	Population of England and Wales.	Years.	Population of England and Wales.
1700	5,475,000	1760	6,736,000
1710	5,240,000	1770	7,428,000
1720	5,565,000	1780	7,953,000
1730	5,796,000	1790	8,675,000
1740	6,064,000	1801	8,872,000
1750	6,467,000		

The population for 1801 was determined by actual enumeration; and since then censuses have been taken in 1811, 1821, and 1831, the results of which are embodied in the following comprehensive table.

---

[1] Exclusive of L.34,521. 7s. 10d. the annual charge on capitals and long annuities, standing in the names of the National Debt Commissioners, on account of stock unclaimed ten years or upwards, and of unclaimed dividends; and also on account of donations and bequests.

Statistics.

Houses; occupations; sexes.

The following table contains an account of the houses inhabited, building, and uninhabited, the number of families, the distribution of families according to their occupations, with the number of males and the number of females, in England and Wales in the year 1821. It is necessary, however, to observe that the classification of employments is not in any degree to be depended upon; but as it has been frequently referred to, we think it right to lay it before the reader. A much more scientific and elaborate classification of employments was made under the census of 1831; but the results have not hitherto been published.

Summary of Houses, Families, Occupations, and Persons, in 1821.

COUNTIES.	HOUSES.				OCCUPATIONS.			PERSONS.		
	Inhabited.	By how many Families occupied.	Building.	Uninhabited.	Families chiefly employed in Agriculture.	Families chiefly employed in Trade, Manufactures, or Handicraft.	All other Families not comprised in the two preceding Classes.	Males.	Females.	Total of Persons.

Rate of mortality, &c.

Notwithstanding the defective state of the registers of marriages, births, and deaths, the results deduced from them are such as to establish beyond all question the fact of an extraordinary improvement having taken place in the healthiness of the mass of the people. Although about 919,000 were added to the population of England and Wales in the interval between 1780 and 1800, the annual average number of burials did not differ materially during that period.[1] It appears from the returns, that in 1780 the rate of mortality in England and Wales was one in forty; meaning by this, that one fortieth part of the whole population died annually. In 1790 the rate of mortality was reduced to one in forty-five. During the five years ending with 1800, it was one in forty-eight; during the five years ending with 1810, one in fifty-one; and during the five years ending with 1820, it had sunk to one in fifty-seven. During the five years ending with 1830, it seems to have slightly increased; having been, at an average of that period, one in fifty-four. See the subjoined table.

This extraordinary decrease of mortality is no doubt owing to a variety of causes; such as, the greater prevalence of habits of sobriety and cleanliness; the better lodging, feeding, and clothing of the labouring classes; improvements in medical science, &c. But to whatever it may be owing, it affords unquestionable evidence of the signally improved condition of the population.

The increase of longevity has been particularly conspicuous in London and other great towns. During the first half of last century, the mortality in the metropolis is believed to have been as high as one in twenty-four; and it required, down to the American war, large supplies of recruits from the country to keep up its numbers. But from 1770 the rate of mortality has been gradually diminishing. In 1790 the births for the first time exceeded the burials; and since then the city would have gone on increasing, though it had not been indebted to the country for a single immigrant. In Manchester, Bristol, &c. the improvement has been equally striking.

The proportion of births and marriages to the population has continued pretty nearly stationary since 1790. We subjoin a table of the annual proportion of baptisms, burials, and marriages, to the population of England; calculated upon an average of the totals of such baptisms, burials, and marriages in the five years preceding the several enumerations of 1801, 1811, 1821, and 1831, and distinguishing the several counties.

[1] Preliminary Remarks to Census of 1821. p. 26.

XV.—*Crimes in England and Wales.*

Crimes of violence have greatly decreased in England during the last half century. Highway robbery, once so prevalent, is now almost unknown; and though murders are occasionally perpetrated, they are not numerous compared with the amount of population. Latterly, however, the crime of arson has made a great and alarming progress; and, from the facility with which it may be committed, the difficulty of detection, and the destruction of property and life it is almost sure to occasion, no means should be left untried which may tend to arrest its progress. There would seem, from the accounts laid before parliament, to be of late years a very great increase in the offences against property. We believe, however, that much of this increase is apparent only, resulting from the establishment of a police force in most great towns, and from the consequent commitment and punishment of numerous culprits who were formerly allowed to escape. The law of England as to capital punishments has recently been much modified; and various opinions are entertained as to what will be the effect of the change. It has, however, been too recently effected, to allow of any inferences being drawn as to its practical operation. The subjoined tables give a very complete view of the state of crime in England and Wales during the seven years ending with 1832.
